## **SECTION 1**

### **SAFETY INFORMATION**

#### **WARNING.**

Any person performing the procedures described in this manual will be exposed to hazardous voltages and the risk of electric shock.

Carver Corporation assumes that any person who removes the cover from the unit has been properly trained in protecting against avoidable injury and shock.

Therefore, the procedures described here are to be performed by qualified electronics service personnel only.

We recommend that the unit be tested only when line isolation is provided by an isolation transformer. The line cord of the unit must be disconnected and the power supply fully discharged before any components are replaced. Failure to do so may result in severe damage to the unit and the risk of electric shock.

The safety tests described below must be performed properly.

#### **CAUTION:**

Before returning the unit to the customer, one of the following safety tests must be performed.

1. Check the leakage current. Connect the unit to 120 VAC supply and turn the power switch "ON". Using an ammeter, measure the current between the neutral side of the AC supply and chassis ground of the unit under test. If leakage current exceeds 0.5mA, the unit is defective.  
Reverse the polarity of the AC supply and repeat.
2. Measure the resistance from either side of the linecord to chassis ground. If it is less than 500k ohms, the unit is defective.

**WARNING - DO NOT** return the unit to the customer if it fails one of these tests until the problem is located and corrected.

#### **CAUTION**

The lightning flash with arrowhead symbol within an equilateral triangle is intended to alert the user to the presence of uninsulated "dangerous voltage" within the product's enclosure, that may be of sufficient magnitude to constitute a risk of electric shock to persons.

The exclamation point within an equilateral triangle is intended to alert the user of the presence of important operating and maintenance (servicing) instructions in the literature accompanying the appliance.

## **SECTION 2**

### **INTRODUCTION**

This manual is intended for use by qualified, authorized personnel only.

Due to the unique and complex circuit designs of Carver Corporation, the following procedure is recommended to diagnose & repair problems with speed and accuracy.

The best way to figure out what is wrong is to learn what is working properly first. Then, through the process of elimination, the defective area can be located. Upon locating the defective area, you then would use your own preferred troubleshooting skills.

The removal of parts for testing, should be kept to an absolute minimum. "In circuit" analysis should provide you with enough data to determine correct operation.

Refer to the design history section of the service manual if you locate a part in the circuit that is not the same as the schematic. This section will be of great assistance to you in performing a correct repair.

At Carver Corporation we continually strive for the most reliable, cost-efficient product available.

When updates and service bulletins are sent to you, please take the time to review them and insert them into the correct service manuals.

The Silver 7t was released in March of 1989 and manufactured until April of 1990. It was originally the Anodized Gray color that was characteristic of the Carver product line throughout the 1980's.

About halfway through its production the color was changed to Painted Black, which is now characteristic of the Carver product line in the 1990's.

The Silver 9t was released in April of 1991. The basic amplifier design is the same as the Silver 7t; however, many cosmetic and auxiliary circuit changes were made, including the addition of a lighted meter. Therefore, you will find separate schematics, board layout drawings and parts lists for the Silver 7t and the Silver 9t in this service manual. Please be sure you are referring to the drawings and parts lists that correspond to the model being serviced.

## **SECTION 3**

### **SPECIFICATIONS**

#### **Specifications for the Silver 7t/Silver 9t**

##### **Power Output:**

Continuous Average Output Power: 575 watts into 8Ω from 20 Hz to 20 kHz  
900 watts into 4Ω from 20 Hz to 20 kHz  
1000 watts into 2Ω from 20Hz to 20 kHz

Power at Clipping: 612 watts into 8Ω at 1 kHz

##### **Dynamic Headroom:**

1.0dB @ 8 ohms  
1.2dB @ 4 ohms

##### **Frequency Response:**

20Hz to 20kHz (± 0.5dB S7t)  
(± 1.0dB S9t)

##### **T.H.D.:**

Less than 0.5% 20Hz to 10kHz

##### **IM Distortion:**

Less than 0.15%

##### **Noise:**

-100 dB A-weighted, referenced to rated power  
-78 dBW A-weighted, referenced to 1 watt.

##### **Input Impedance:**

115kΩ

##### **Sensitivity:**

2.3V rms for rated power into 8 ohms

##### **Damping Factor:**

Greater than 7 (S7t)  
Greater than 125 (S9t)

##### **Gain:**

29.0dB

##### **Display:**

Analog Meter - VU response

##### **Power Consumption:**

1400W at full power

##### **Power Requirements:**

120VAC/60Hz (USA and Canada)  
230VAC/50Hz (Europe)

##### **Dimensions:**

11.5" W x 7.0"H x 14.5"D  
292mm x 178mm x 368mm

##### **Weight:**

19.5 lbs  
8.8 kg

**Test Note:** Accurate measurement depends on a sufficiently "stiff" AC supply. The 60 Hz AC line distortion must be below IHF specifications.

## SECTION 4

### CIRCUIT DESCRIPTION SILVER 7t/SILVER 9t

#### TECHNICAL DESCRIPTION

The unconventional design of this amplifier is described in the following circuit description. Read this information carefully before attempting to repair this unit.

This circuit description applies to both the Silver 7t and the Silver 9t amplifiers. Any part of the circuit that is unique to the Silver 7t or the Silver 9t will be identified as such.

The Silver 7t and Silver 9t series of amplifiers consist of the following types of circuit boards:

- \* Amplifier
- \* Primary Circuit and Regulator
- \* Main Power Supply and Protection Circuits
- \* Meter Drive
- \* Meter Light (Silver 9t only)

Refer to the Block Diagram in Section 7 for an illustration of the functional relationships between system components, and to the complete schematic diagrams for the Amplifier, Power Supply, Regulator and Meter Boards in Section 8.

#### Primary Circuit and Regulator Board

The amplifier is fused with an MDA 12 amp fuse on the 115 V units and an MDA 6-1/4 amp fuse on 230V units.

The amplifier is thermally protected by a heatsink mounted 100° C self-resetable thermal breaker in series with the transformer power control circuitry. There is also an internal 150° C resetable thermal switch inside the transformer, in series with primary.

A line filter minimizes normal and common mode noise on the AC line between 0.15 and 30 MHz. It is also used to suppress noise generated by the triac conduction from the AC line.

A voltage conversion switch rewires the transformer primary from a parallel to a series configuration for 230 V operation (Silver 7t only; Silver 9t uses jumper wires).

#### Start-up Sequence

The phase shift voltage at the junction of R8 and R2 is obtained through the heatsink thermal switch and is approximately 110-120V, regardless of whether the amplifier is configured for 115V or 230V operation.

When the power switch on the front of the amplifier is off, it shorts the connection between D and E on the Regulator Board, preventing the phase shift capacitor C4 from charging up.) Once the power switch is turned on, capacitor C4 begins charging up through R8 and either Q2 or Q3, depending on the polarity. The positive half-cycle of the AC line will charge C4 through R8 and Q3. This charging current forward biases the base emitter junction of Q3, causing it to conduct. Q3 turns on Q4, but no gate current can flow because D6 is reverse biased. C4 continues charging until the charge on C4 exceeds the now falling voltage at the junction of the bases of Q2 and Q3, formed by divider R8 and R9. Q3 and Q4 will turn off and C4 will begin to discharge through Q2 because the junction of R8 and R9 is more negative than the emitter of Q3 (C4). Q2 will conduct and turn on Q1, and gate current will flow through forward biased D5, firing and latching the triac. On the negative half cycle, C4 is charged through Q2 and discharged through Q3, Q4, D6 and R10 into the gate of the triac. The triac begins to conduct at a minimum phase angle and applies 30-40 VAC to the primary of the transformer.

The triac is switched on and off every half-cycle of the 60Hz AC line. Thus, the triac switches the AC line current off at a rate twice the line frequency, at

the instant the line current crosses the zero axis. The triac will then remain off for a number of degrees of the sinusoid, before switching on again. The phase angle at which the triac switches on is the "firing angle" of the triac.

This produces enough voltage to the primary of the power transformer to allow the secondary regulator stage on the power supply board to begin to operate.

### Power Supply Regulation

The firing angle of the triac controls the voltage on the primary of the transformer, and is determined by the conduction of the optocoupler U1 on the Regulator Board.

As the conduction of the optocoupler increases, the amount of phase shift on C4 decreases, which increases the conduction angle of the triac. The phototransistor conduction of the optocoupler is controlled by the current through the LED portion of the optocoupler. This LED current is supplied by U1-7 on the power supply board. This differential amplifier senses the secondary supply voltages through R1, R4, R5 and R7. The output voltage at U1-7 increases at the rate determined by C3 (slow start-up). The photo-transistor in the optocoupler will begin to conduct and charge C4 on the regulator board at a faster rate through R2 and D1/D4 or D2/D3 "steering" diodes, depending on the polarity. This decrease in phase shift results in a longer triac conduction time and higher secondary voltages. The idle secondary voltages are set by RP1 on the power supply board.

### Load Regulation

When the amplifier is driven into a load, the DC supplies (rail voltages) will begin to "sag". Differential amplifier U1-7 senses this and increases the LED current to the optocoupler. This action increases the phototransistor conduction, which increases the triac conduction, which increases the primary voltage, which increases the secondary voltages, thus providing steady, regulated DC supplies for the amplifier stage.

### Secondary Voltages

The secondary winding of the power transformer has three taps that supply the three pairs of DC supply voltages ( $\pm 118V$ ,  $\pm 67V$ ,  $\pm 31V$ ), each having its own set of bridge rectifiers and filter capacitors.

Parallel load resistors R43 and R51 on the 31V bridge rectifier insure that the triac remains latched by providing primary holding current after the secondary supply rectifiers stop conducting.

The  $\pm 11.4Vdc$  supply are derived from the  $\pm 31V$  dc supply, and regulated by Q9, Q10 and 12V zener diodes D22 and D23. Resistors R44, R46, R49 and R54 provide a residual DC voltage after the unit is turned off, thus keeping the front end of the amplifier biased up to prevent excessive thumping. The  $\pm 11.4Vdc$  supply powers the op-amps and small-signal transistors.

The  $+15V/-13Vdc$  supply is also derived from the  $\pm 31Vdc$  supply. The  $+15V$  supply is regulated by R48 and 15V zener diode D26. The  $-13V$  supply is derived from the voltage divider R50 and R59. The  $+15V/-13Vdc$  supply powers the meter board and power LED.

### Amplifier Stage:

A single standard phono plug on the rear of the amplifier is hard-wired to the power supply board. The signal is transferred to the amplifier board via connector J2.

An N-channel FET (Q1) mutes the input approximately -30dB during turn-on or during a fault condition. The FET drive circuit is located on the power supply board.

Input buffer U1 is a TLO-81 operational amplifier, which provides a high input impedance and a low output impedance for driving the succeeding amplifier stage. Local negative feedback from the output of U1 via R14 and C15 is used for stability and to reduce overall negative feedback.

The output of the input buffer U1 is coupled to Q2 and Q3 which in turn provide a current source for DC biasing, as well as provide DC-level shifting. The latter is required for referencing the audio signal to the top DC supplies to drive the next stage, predrivers and drivers.

The output of the DC-level shifters drives a pair of predriver voltage amplifiers (Q4/Q26 and Q7/Q27). This stage provides full voltage swing to the following current gain stages and also provides "tracking" to the commutator circuits.

The bias network of Q5 and Q6 provides adjustment of the DC idle current through outputs Q20/Q32 and Q22/Q34. Q6 is mounted on the heatsink and provides feedback to prevent thermal runaway and helps maintain a constant idle current. RP1 adjusts the idle current by varying the base voltage at Q6.

The predrivers (Q4/Q26 and Q7/Q27) drive the "driver" stage (Q11/Q28 and Q12/Q33), which in turn provides current amplification for driving the outputs and supply commutating circuitry.

Q9 and Q10 limit the current available to the base of the drivers. These transistors are biased on by the voltage drop across the output emitter resistors, R94 and R95. When Q9 is conducting, it provides a shutdown signal to the power supply board and mute circuitry. (See High Frequency Output for details.)

Current from Q11/Q28 and Q12/Q33 drives the two parallel pairs of high gain, high-linearity output devices Q20/Q32 and Q22/Q34. These devices provide full voltage swing and current drive to the loads.

The active, local bias network of Q21, R87, and R88, provides variable "pull down" of the bases of Q20/Q32 and Q22/Q34 to help prevent common-mode conduction of the output transistors and reduce their turn-off time.

The TFM (Transfer Function Modification) circuitry for the Silver 7t is composed of IC U2, which detects the output current by differentially detecting the voltage drop across R97/R53. When an 8Ω load is connected to the amplifier output, the output of U2 reduces the overall gain of the amplifier by approximately 1dB. The combination of R97/R53 and the 0.2Ω 20W parallel resistors on the output speaker terminal provides a relatively high output impedance and a low damping factor.

The TFM circuitry for the Silver 9t is somewhat different than the Silver 7t. IC U2 acts as an inductor in a gyrator circuit, and provides a low frequency boost of about 1dB below 100Hz. The output resistors R97/R53 and the 0.2Ω 20W parallel resistors have been removed to lower the output impedance and increase the damping for a "tighter" bass sound.

## Power Supply Commutators

The first supply commutator transistors, Q19/Q31 and Q23/Q35, are used to increase the supply voltages on the collectors of Q20/Q32 and Q22/Q34 from 31 V to 67 V as required.

The diode network of D18, D19, and D20 (and their negative equivalents), in the base of Q20/Q32 and Q22/Q34, provides voltage "lead" for the first supply commutating transistors (Q19/Q31 and Q23/Q35). This allows the supply voltages to anticipate audio demand. As frequency increases, Q20/Q32 and Q22/Q34 require additional "lead"

time to stay ahead of the audio. This is achieved by C22, R60 and D17 (and their negative equivalents).

The second supply commutator pairs (Q17/Q18/Q29/Q30 and Q24/Q25/Q36/Q37) increase the supply voltages on the collectors of Q19/Q31 and Q23/Q35 to increase Q20/Q32 and Q22/Q34 collector voltages to 118 V (no load), as required. (See Figure 4 in Section 8.)

D29 and D30 prevent the first commutator from dumping back into the 31V supply. The second commutators receive their drive from drivers Q14 and Q16.

However, the current at this stage is insufficient to supply enough current to the output transistors and a bootstrap network and current gain stage are required. The main bootstrap network consist of R49, R52, R62, and C19 (and their equivalents on the negative side).

The turn-on threshold for the second commutators is determined by the DC biasing on the base of Q13 and Q15.

D28 and D31 provide supply steering which prevents the commutators from dumping back into the 67V supply.

## Protection Circuitry

Protection functions are shared by the amplifier and the power supply. Active shutdown protection is provided for the following faults.

### Over current:

The amplifiers are protected from short-term excess current through the output stage by electronic current-limiters. When the current through the output transistors becomes excessive, the voltage drop across the emitter resistors R94 and R95 bias the current limiter transistors Q9 and Q10 on, which shunt the drive current via D7 and D9. Q9 provides base current for Q2 on the Power Supply Board through D8 and R37, which drives Q3. Q3 then charges C11 and turns on Q8, which supplies a negative turn-off voltage to the input muting FET on the amp board. This attenuates the input signal, removing the high current condition, turning off all but Q8, which turns off about four seconds later, after C11 discharges through R35 and R34; thus turning off the muting FET's and allowing signal to pass. In this way, the short circuit current is briefly limited to 16 amps until the mute circuit is activated. R56, D13, R57 and D14

determine the V-I limits. The limiters should not activate into loads of 2 ohms or greater with no more than 45° phase shift.

#### DC Offset:

DC offset is sensed by a low-pass differential amplifier located on the power supply board, formed by U1-pins 2 and 3. The capacitor C6 rolls off the output in the audio spectrum while  $\pm$  DC offset and low frequency signals below 5 Hz are amplified. If pin 1 goes positive, current through D6, R18, and U1-6 drives the output of U1-7 negative. This reverse biases the optocoupler LED on the Regulator Board and forces the conduction angle of the triac back to its initial startup position, thereby lowering all secondary power supply voltages and insuring the offset is held to a minimum value.

#### High Frequency Output:

The amplifier drives to clipping up to 20 KHz. At 40 KHz the amplifier drives to approximately 50Vrms, or about 3dB below clipping. C11 on the Amplifier Board forward biases limiter transistor Q9 during negative transitions. Q9 provides base current for Q2 on the Power Supply Board, thus initiating the input muting circuit. This attenuates the high-frequency signal, allowing the mute circuit to reset after a few seconds.

#### Low-Level Supply:

D2 and D3, on the Power Supply Board, insure that the output of U1-7 never goes to its maximum positive state if either the -11.4 or -13 VDC supplies are shorted out.

If the output of U1 were to reach its maximum (+10 to +11 V) at idle, the triac would shift to its maximum conduction angle and cause overvoltage in the 115V, 67V, and 31V DC supplies.

Any +11.4 Vdc supply fault causes DC offset at the amplifier output. (See DC Offset for a full description of the protective mechanism involved.)

#### Overheated Output Transistors:

A 100° C resetable thermal switch, in series with the AC line control circuitry, protects the output transistors if the air vents are blocked or if the unit is run with excessive continuous sinewaves.

#### Overheated Transformer:

A 150° C resetable thermal switch is located inside the power transformer. This switch protects the transformer if the amplifier is overfused or has been run for an extended period of time at excessive power output levels.

#### Major Faults:

The slo-blo line fuse protects the unit from further damage when a major fault such as a shorted triac, shorted transformer, or a major secondary power supply fault occurs.

If the unit is run at or near its rated power, the fuse eventually blows. The rated line fuse allows the unit to be operated without interruption for all musical applications.

#### Meter Board:

The meter drive PCB provides logarithmic DC rectification of the signal coming directly from the amplifier output.

Resistors R1, R2, R3 and transistor Q1 create a variable attenuator to reduce the signal to a usable level, while U1-1 and U1-7 add a fixed gain of about 53dB. D1 rectifies the output of U1-7, and this dc level is used to bias transistor Q1. The larger the signal, the more Q1 is biased on which increases the attenuation of the R1/R2/R3/Q1 network, causing a 2:1 gain compression of the signal. RP1 is used to adjust the dc bias on Q1 to calibrate the meter.

This logarithmic signal is fed to the base of Q2 which rectifies the signal and charges C4. Resistors R10-R12 attenuate the dc level to reduce the current through the meter, and in conjunction with capacitors C5, C6 and C11 provide the meter with a VU type response. Therefore the ballistics of the meter will present an averaged response to the program material.

## **SECTION 5**

### **TEST PROCEDURE**

#### **Silver 7t/Silver 9t**

Use the test procedure described in this section to determine the overall performance of the amplifier. Before beginning the test, read the troubleshooting section to review the types of problems that may be identified by the test. Steps 7 and 8 of the performance test must be completed to ensure the unit meets general safety requirements.

If you do not understand any of the following procedures, or if you do not have the equipment required to complete the tests, please contact the factory.

#### **Disassembly Procedure:**

To remove Top Cover Assembly (includes Top Panel, Back Cover, Back Housing and Meter Housing):

1. Remove 10 screws (5 on each side) around the bottom perimeter of the Top Cover Assembly.
2. Lift Top Cover Assembly away from chassis.

#### **To remove Chassis Top:**

1. Remove 11 screws from the bottom of the unit , securing chassis top to chassis bottom (9 on one side, 2 on the other side).
2. Slide chassis top forward about 4 inches.
3. Remove wires from the meter. Make a note of the polarity of the wires for reinstalling.  
Note: On the Silver 9t, remove the cable tie around the middle of the black and red twisted pair between the power supply board and the meter light board to allow it to extend to its full length.
4. Carefully slide the Chassis Top forward until it clears the front edge of the Chassis Bottom.
5. Set the Chassis Top on its right side next to the Chassis Bottom.

### **Required Equipment:**

Oscilloscope(s)      Note: We recommend the use of two scopes. One scope should be isolated, with no secondary ground reference. Use this scope to observe triac waveforms on the AC line. The second scope can be used to observe the amplifier output and for secondary troubleshooting.

Distortion Analyzer

Variac, 20-30 amp

AC line current monitor

AC line voltage monitor

Two 4Ω load resistors, 500W each (or equivalent)

Digital voltmeter

AC voltmeter

Safety Analyzer (Hi-Pot Tester)

### **Presets:**

Follow the procedure described below to power up a damaged unit:

- A) Connect an 8 ohm load to the output terminals.
- B) Connect an input cable to the input jack from the distortion analyzer signal output (set to 2kHz).
- C) Set the Variac to minimum.
- D) Set RP1 on the Power Supply Board for minimum VDC (turn the potentiometer fully counter-clockwise).
- E) Set RP1 on the Amplifier Board for minimum idle current (turn the potentiometer fully clockwise).
- F) Set the Audio generator to minimum.

### **Step-by-Step Procedure:**

#### **CAUTION**

All primary waveforms must be viewed with an isolated, line triggered scope with no secondary ground reference.

**Step 1.** Bring the variac up slowly to approximately 60 VAC line (or to 120 VAC for 230 V units).

- A) AC current flow in line should be less than 0.25 amps.
- B) The start up voltages should be as follows:
  - 1) 118VDC supplies should be approximately 20VDC.
  - 2) 11.4 VDC supplies should be approximately 2-3VDC.
- C) Check amplifier output for DC offset less than 100 mV.

**Step 2.** Bring up the variac to approximately 85 VAC line (or to 170 VAC for 230 V units).

- A) Triac fires and there is a momentary surge of current.
- B) AC current flow in line should be less than 0.5 amps.
- C) Increase audio input to generate a 1 Vrms 2kHz signal at the amplifier output. Small crossover notches should be present on sine wave output.
- D) Check triac firing for good symmetry (see Figure 1).

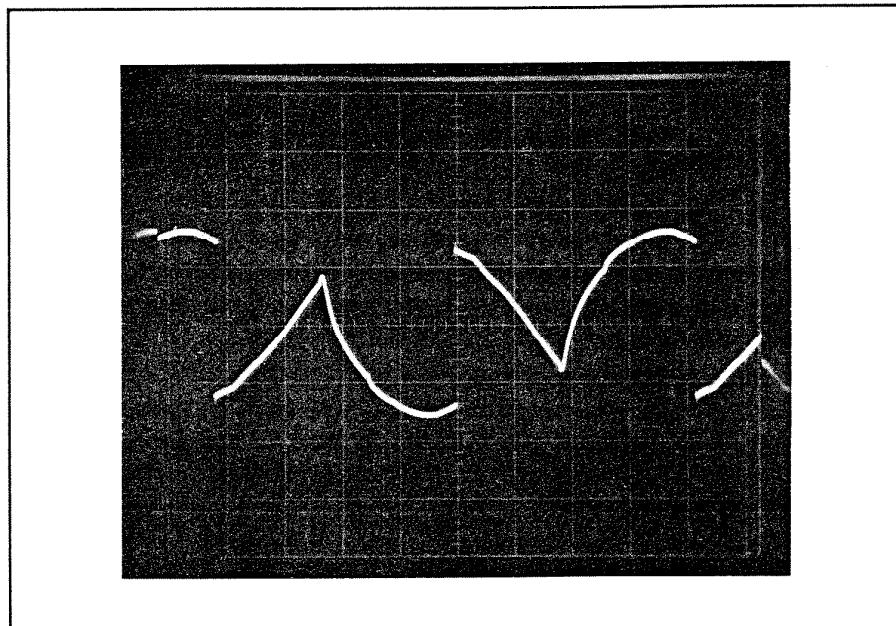

Figure 1: Triac conduction at idle, viewed at MT2.  
(50V/div. Vertical; 2mS/div. Horizontal; Line Sync)

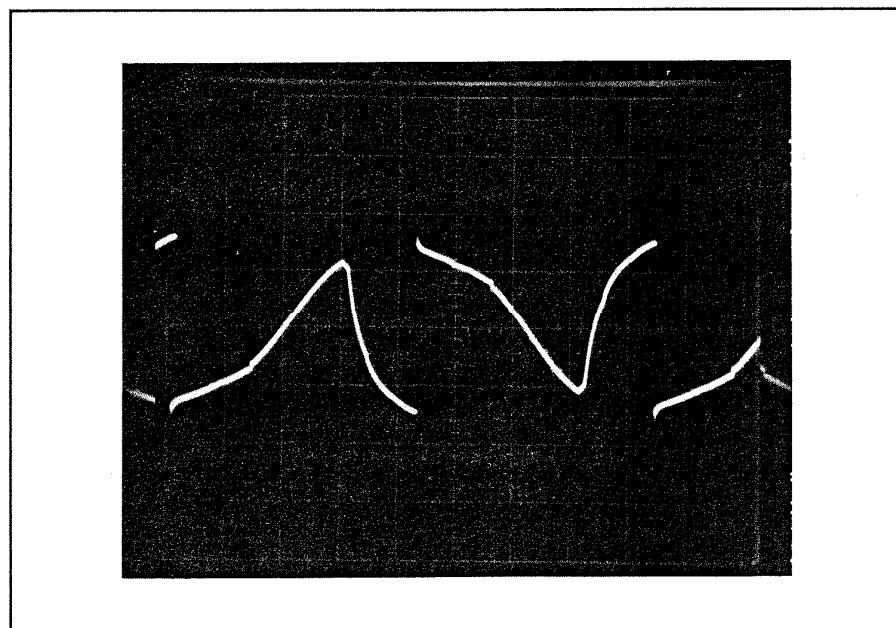

Figure 2: Triac conduction at full power, viewed at MT2.  
(50V/div. Vertical; 2mS/div. Horizontal; Line Sync)

- E) Check all VDC supply levels for power supply regulation:
  - 1) 118 VDC supplies should be approximately 92 VDC.
  - 2) 67 VDC supplies should be approximately 51 VDC.
  - 3) 31 VDC supplies should be approximately 23 VDC.
  - 4) 11.4 VDC supplies should be approximately 11.4 VDC.
  - 5) 13 VDC supplies should be approximately 8-9 VDC.
- F) Amplifier offset should be less than 30 mV.

**Step 3.** Increase Variac to 120 VAC (or 230 V for 230 V units).

- A) AC current flow should be less than 1.0 amp.
- B) 118 VDC supply should be approximately 97 VDC.

**Step 4.** Adjust RP1 on the Power Supply Board to obtain a top rail voltage of 118VDC.

- A) Observe normal triac conduction at idle point (See Figure 1).

**Step 5.** Set Amplifier Idle Current.

Note: This adjustment should be made after the unit has been on at least two minutes at idle.

- A) Turn off the input signal.
- B) Adjust RP1 on the Amplifier Board for 2.5mV with meter bridged across both 0.05 ohm, 5W emitter resistors, R94 and R95.

**Step 6.** Amplifier Board.

A) Check frequency response:

- 1) Set output reference to +10dBV (3.16Vrms) at 2kHz.
- 2) Check response at 20Hz and 20kHz. See Figure 3.  
S7t: (+0, -0.5 dB)  
S9t: (+1.0, -0.5dB)

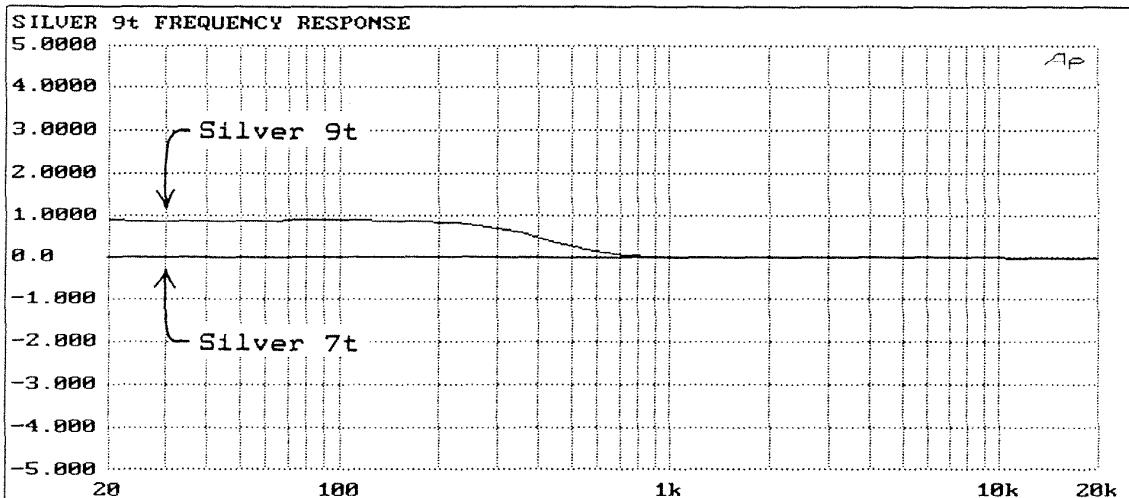

Figure 3: Frequency Response

B1) Adjust Damping (S7t only)

- 1) Connect an 8Ω load to the output.
- 2) Adjust the signal generator to produce a -29dBV (35.5mV rms) signal at 2kHz.
- 3) Adjust RP2 on the amp board to produce a 0dBV (1V rms) output into an 8Ω load.

B2) Check Gain (S9t only)

- 1) Adjust the signal generator to produce a -29dBV (35.5mV rms) signal at 2kHz.
- 2) Verify the output is 0dBV ( $\pm$  1dB) into an 8Ω load.

C) Check damping at 2kHz.

S7t: Output should drop 1.0dB (+/-0.1dB) from no load to 8 ohm load.  
S9t: Output should drop less than 0.1dB from no load to 8 ohm load.

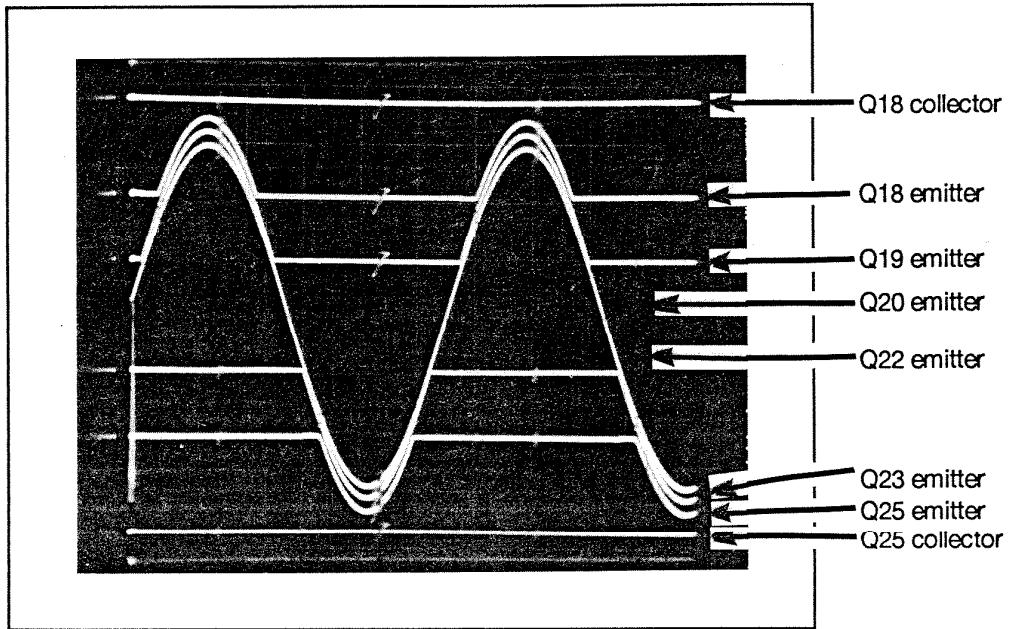

Figure 4: Commutators

- D) Increase amplifier output to 67.8 Vrms (575W/8Ω). The commutators should appear as in Figure 4 at 2kHz.

**NOTE:** The AC line current will exceed the rated value of the line fuse when the amplifier is driven to full power. Since the fuse is slow-blowing, it can withstand the higher current for a few seconds before blowing. Therefore, these tests should be performed quickly to avoid blowing the fuse.

It may be necessary to temporarily replace the 12A line fuse with a 15A slo-blow fuse.  
**DO NOT forget to return the 12A fuse after completing these tests!**

Note the maximum triac conduction angle shown in Figure 2.

- E) Check full power into 8 ohms at 2kHz.

**NOTE:** A sufficiently low-impedance AC supply is required to achieve low distortion measurements at full power. If the AC line voltage "sags" at full power, it may be necessary to increase the Variac to bring the line voltage back up to 120VAC.

- 1) Distortion at 575 watts per channel should be less than 0.5% (see Figure 5).
- 2) Repeat at 20Hz and 10kHz.

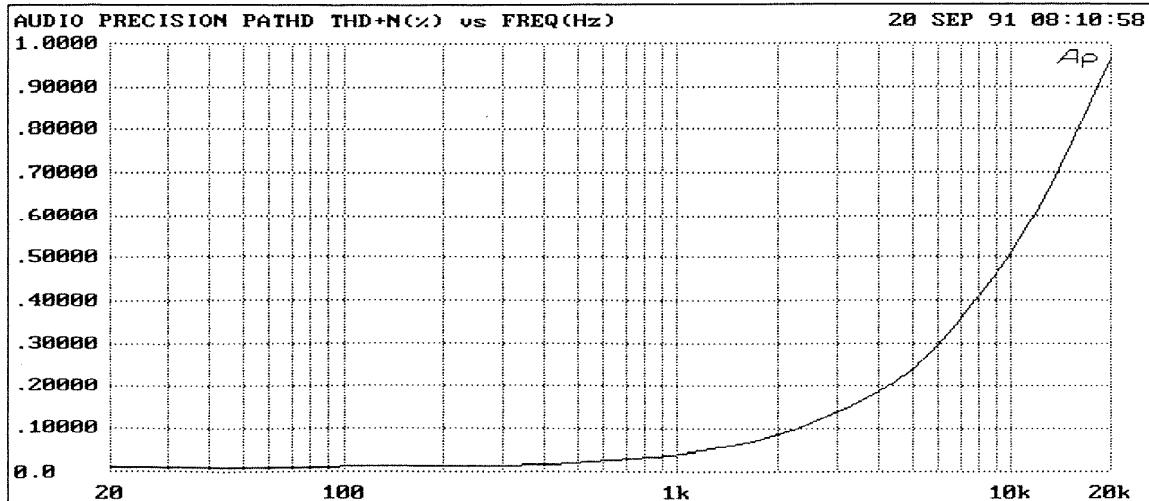

Figure 5: THD vs. Frequency at full power (575W/8Ω)

- 3) Increase output to 600W at 2kHz and verify symmetrical clipping on the positive and negative peaks of the waveform.
- F) Check full power into 4 ohms at 2kHz.
  - 1) Connect a 4 ohm load to the output terminals and increase the input until the output is just below clipping. This should be about 900W (60Vrms/4Ω).
- G) Check full power into 2 ohms at 2kHz.
  - 1) Connect a 2 ohm load to the output terminals and increase the input until the output is just below clipping. This should be about 1000W (44.7Vrms/2Ω).
- H) High-Frequency Shutdown
  - 1) Turn signal generator down and set to 40kHz. Connect an 8 ohm load to the output terminals. Slowly increase the input to the amplifier and verify the output exceeds 40Vrms before the amplifier mutes (typically at about 50Vrms output).
- I) Short circuit protection:
  - 1) Adjust input level for 20 Vrms output at 2kHz.
  - 2) Short the output to ground.
    - a) The amplifier should mute immediately.
    - b) One mute cycle should last approximately 6 to 8 seconds. Normal operation should return when short is removed.
- J) Noise, with input shorted:
  - 1) A-weighted noise should be less than 100 dB below rated power (< 675uV) or less than 95dB below rated power unweighted (<1.2mV unweighted).
- K) Check turn-off and turn-on thump, and turn-on delay.
  - 1) Increase input level at 2kHz to 0dBV output.
  - 2) Turn the amplifier off and verify a thump of less than 2Vrms (monitor for at least ten seconds).
  - 3) Turn the unit back on and verify less than 1Vrms thump, and the signal reappears between 4 - 10 seconds.
- L) Meter Calibration
  - 1) Set the input signal level for 68.7Vrms output into 8 ohms (575W/8Ω).
  - 2) Adjust RP1 on the meter board for a reading of 0dB (575 watts) on the meter.
  - 3) Check that both meter lamps are lit (Silver 9t only).

**Step 7. Line Leakage:**

With an approved safety analyzer, verify line leakage is less than 500µA from both high and low sides of the line to chassis ground.

**Step 8. Dielectric Breakdown:**

With a calibrated and approved tester, verify that the unit can withstand application of a 1000 VAC signal for at least one second.

Apply the signal between either side of the line and an exposed ground on the unit. The power switch should be ON.

## **SECTION 6**

### **TROUBLESHOOTING GUIDE**

The Silver 7t/Silver 9t amplifiers are more complex than a conventional amplifier. This guide will help service technicians isolate and repair electrical faults in the amplifier.

Major faults should be investigated with the loads removed.

#### **CAUTION**

All primary waveforms must be viewed with an isolated, line triggered scope with no secondary ground reference.

#### **Fault 1: No Power.**

No Power LED Light at 120 VAC Line.

No AC Current.

- 1) Determine if AC line voltage is reaching the triac.  
Use AC voltmeter from MT1 to MT2 on triac.
- 2) If AC is not present on triac:
  - a) Check fuse and fuse holder.
  - b) Check line cord.
  - c) Check voltage conversion switch on regulator board (Silver 7t only).
  - d) Check primary winding of transformer for continuity. There is an internal thermal switch in the primary winding.
- 3) If AC is present across triac (MT1-MT2), but triac is not firing:
  - a) Check for phase shift voltage across C4 on regulator board.
  - b) If voltage is not present, either:
    - \* The Power Switch is shorted
    - \* Resistor R8 is open on the Regulator Board.
    - \* Q2 and Q3 are defective on the Regulator Board.
    - \* Check thermal switch on heatsink.
  - c) If voltage is present, either:
    - \* Resistor R10 is open on the Regulator Board.
    - \* The triac is defective.
    - \* Q1 and Q4 are open on the Regulator Board.
    - \* D5 and D6 are open on the Regulator Board.
- 4) Triac fires and the voltage at C4 is less than 4 Vrms.  
All power supplies remain low.
  - a) Opto-coupler CNY-17-2 is defective.
  - b) D1 through D4 are defective on the Regulator Board.
  - c) U1 is defective on the Power Supply Board.
  - d) Resistors associated with U1 are defective.
  - e) Check R2 and R3 on the Regulator Board.
  - f) See Fault 4.

**Fault 2: Greater Than 1 Amp AC Line Current Draw With Small Variac Rotation.**

- 1) Check the following primary components:
  - a) Triac
  - b) Power transformer
  - c) Line filter
  - d) Voltage conversion switch (Silver 7t only)
- 2) Check scope isolation.
- 3) Proceed to next section.

**Fault 3: No Output**

**AC Line Current Greater Than 1 Amp After Triac Firing.**

**NOTE:** This condition means that a current drawing fault exists on either the Power Supply Board or the Amplifier Board.

Troubleshooting under these conditions can be simplified by shorting across the triac with a jumper wire. This bypasses the triac control and allows 100% of the line voltage to be applied to the transformer. Therefore, never increase the line voltage beyond about 60 VAC when the triac is bypassed.

**Use Extreme Caution.** Be sure the variac is turned all the way down and unplug the amplifier from the variac. Short across MT1 and MT2, the source and drain of the triac. Do not short the gate of the triac or you may damage the triac and associated circuitry.

- 1) If the Amplifier channel is not offset:
  - a) Check 118 V supply capacitors and rectifiers.
  - b) Check 67 V supply capacitors and rectifiers.

Observing excessive ripple voltage on any DC supply can help locate which supply is faulty.
- 2) If the amplifier output is offset,
  - a) and the offset is positive:
    - \* D23 is shorted on the Power Supply Board.
    - \* C17 is shorted on the Power Supply Board.
    - \* D14 and D15 are shorted on the Power Supply Board.
    - \* C14 is shorted on the Power Supply Board.
    - \* Q20/Q32, Q11/Q28, or Q21 is defective on the Amplifier Board.
    - \* Q6 or Q5 is defective on the Amplifier Board.
    - \* Check the predrivers Q4/Q26 and Q7/Q27 and associated resistors and diodes.
    - \* The mica insulator on the Amplifier Board is defective or missing.
  - b) and the offset is negative:
    - \* D22 is shorted on the Power Supply Board.
    - \* C16 is shorted on the Power Supply Board.
    - \* D16 and D17 are shorted on the Power Supply Board.
    - \* C15 is shorted on the Power Supply Board.
    - \* Q22/Q32, Q12/Q33, or Q21 is defective on the Amplifier Board.
    - \* Q6 or Q5 is defective on the Amplifier Board.
    - \* Check the predrivers Q4/Q26 and Q7/Q27 and associated resistors and diodes.
    - \* The mica insulator on the Amplifier Board is defective or missing.

**Fault 4: No Output****AC Line Current Draw is Less Than 1 Amp.**

- 1) If the amplifier output is offset,
  - a) and the offset is positive:
    - \* U1 is defective if the output is positive and if pin 3 is at ground and pin 1 of U2 on the Amplifier Board is at ground.
    - \* U2 is defective if pin 1 or pin 7 is offset on the Amplifier Board.
    - \* Q2 is shorted or Q3 is open on the Amplifier Board.
    - \* Q4/Q26 is shorted or Q7/Q27 is open on the Amplifier Board.
    - \* R34 is open.
  - b) and the offset is negative:
    - \* U1 is defective if the output is negative and if pin 3 is at ground and pin 1 of U2 on the Amplifier Board is at ground.
    - \* U2 is defective if pin 1 or pin 7 is offset on the Amplifier Board.
    - \* Q3 is shorted or Q2 is open on the Amplifier Board.
    - \* Q7/Q27 is shorted or Q4/Q26 is open on the Amplifier Board.
    - \* R32 is open.

**Fault 5: No Output****Power Supply Regulating. No Signal Amplification.**

- 1) Mute drive defective.
  - a) Q8 on the Power Supply Board is shorted.
  - b) Q2 on the Power Supply Board is shorted.
  - c) Q1 on the Amplifier Board is shorted.
- 2) Defective current limiters.
  - a) Q9 on the Amplifier Board is shorted.
  - b) D7 on the Amplifier Board is shorted.
  - c) R94 or R95 have changed value or opened.
- 3) Disrupted signal path.
  - a) Mute FET Q1 is defective.
  - b) A bad solder joint at C3.
  - c) R3 is open.
  - d) Bad solder joint on the input jack connecting wire.
  - e) R97 is open (S7t only).
  - f) 0.2 ohm 20W resistor (binding post) open (S7t only).

**Fault 6: Distorted Amplification (Commutation and Power Supply Fault)**

- 1) First commutator is not supplying sufficient drive to the outputs:
  - a) Q19/Q31 or Q23/Q35 on the Amplifier Board is defective.
  - b) Either D29 or D30 is shorted. (This short causes the commutator current to flow back into the supply rather than to the output transistors.)
  - c) Insufficient voltage lead for the first commutator.
    - \* Either D18, D19, D20, D21, D22, or D23 is defective.

- 2) Second commutator is not supplying sufficient current to the outputs.
  - a) Either Q17/Q18/Q29/Q30 or Q24/Q25/Q36/Q37 is defective.
  - b) Insufficient drive to Q17/Q18/Q29/Q30 or Q24/Q25/Q36/Q37:
    - \* Check drive transistors Q13, Q14, or Q15, Q16.
    - \* Check bootstrap network D12, D35, C19, R49, R52, R62, or D15, D36, C20, R61, R65.
    - \* Either D28 or D31 is shorted. (This short causes second commutator current to flow back into the 67 V supply instead of to the output transistors.)
  - c) Current limiters are defective.
    - \* Check D7, Q9 or D9, Q10.
  - d) Drive circuitry is defective.
    - \* Check drivers Q11/Q28 and Q12/Q33.
    - \* Check R36 and R40.
    - \* Check predrivers Q4/Q26 and Q7/Q27.
    - \* Check fusible resistors R32 and R34.
    - \* Check fusible resistors R35 and R41.
    - \* Check D6 and D10.
    - \* Check Q2 and Q3.

**Fault 7: Drives No Load Ok. Distorts Into 4-8 ohm Load.**

- 1) Defective drive resistors on the Amplifier Board.
  - a) Check R36, R40, R35, R41, R32, and R34.
  - b) Check R23 and R26.
- 2) Overheated emitter resistors.
  - a) Check output emitter resistors R94 and R95.
  - b) Check commutator emitter resistors R84, R93, R92, and R96.
- 3) Leaky current limit transistors.
  - a) Check Q9 and Q10.
- 4) Defective commutator transistors.
  - a) Check Q17/Q18/Q29/Q30, Q24/Q25/Q36/Q37, Q19/Q31, Q22/Q34.
- 5) Defective commutator drive resistors
  - a) Check R66, R74, R73, and R82.
  - b) Check R49, R52, R62, R61, and R65.

**Fault 8: Incorrect Damping (S7t only)**

- 1) 0.2Ω 20W resistor in series with output is defective.
- 2) R97 on the Amplifier Board is defective.
- 3) U2 or R6-R15 is defective.

### **Fault 9: Excessive Noise**

- 1) Bad TLO-81 op-amp (U1) on the Amplifier Board causes "hiss" or "popcorn" noise.
- 2) Secondary leads from transformer are not routed downward close to the chassis.
- 3) Improper grounding.
  - a) Signal ground and power supply ground are connected somewhere in addition to the common grounding point on the power supply.
  - b) Transformer center tap (black wire), +118 V caps ground (black wire), speaker ground return (black wire) not soldered properly.
- 4) Bad FET Q1 on the Amplifier Board.
- 5) Triac misfiring causes excessive noise.
- 6) See Service Bulletin SST-4.

### **Fault 10: Excessive Turn Off "Thumps"**

- 1) A delayed turn-off thump suggests a defective part in the low dc volt supplies:
  - a) Check R44, R49, R45, R55, R56, Q9 and C16.
  - b) Check R46, R47, R54, R57, R58, Q10 and C17.
- 2) Delayed turn-on and turn-off thumps indicate one of the following:
  - a) Defective TLO 81 on the Amplifier Board.
  - b) Leaky drivers or predrivers (Q4/Q26, Q7/Q27, Q11/Q28, or Q12/Q33).

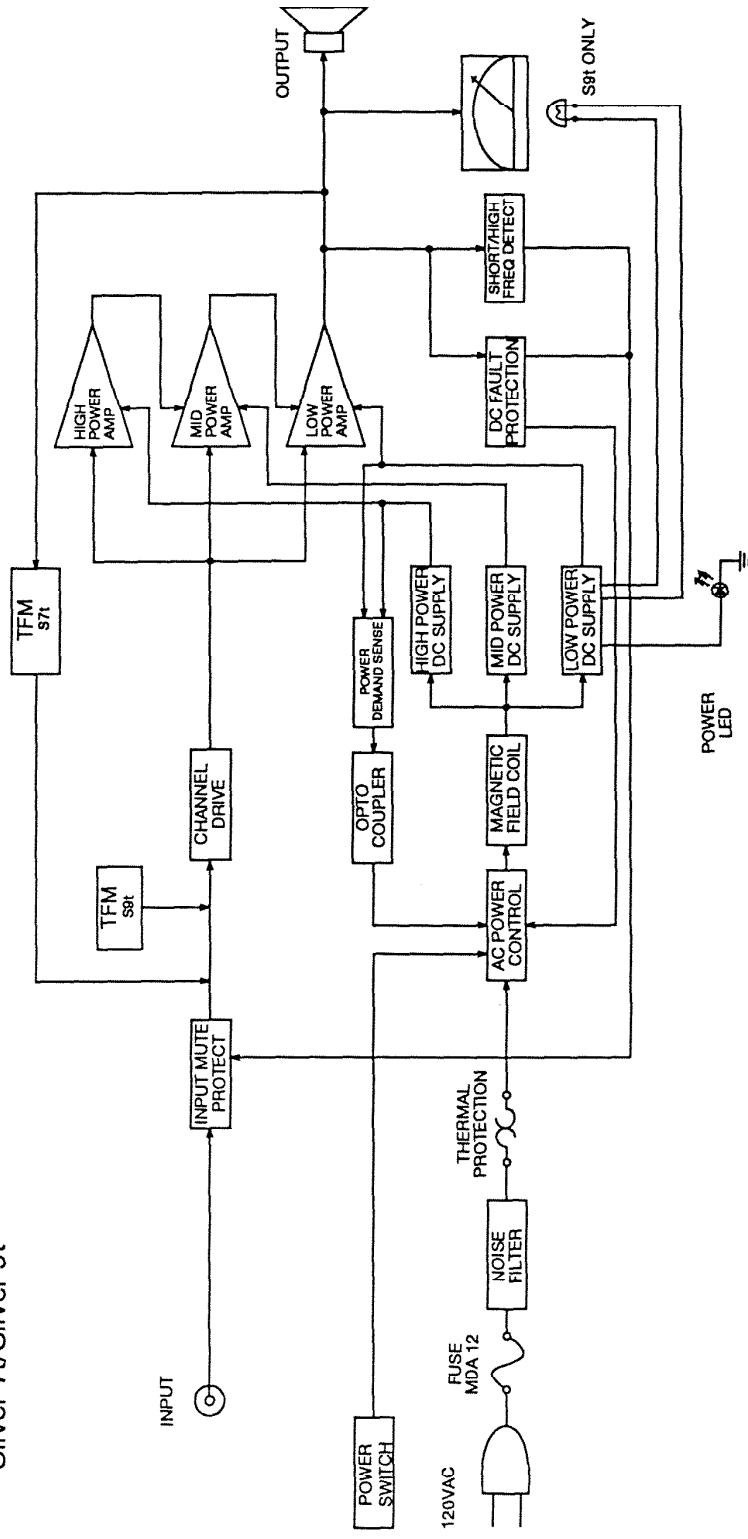

### **Fault 11: High Frequency Oscillation**

- 1) Output RC network at binding posts:
  - a) Check  $2.7\Omega$  5W.
  - b) Check  $0.33\mu\text{f}$  400 V.
- 2) Check the compensation capacitors, specifically:  
Check C18, C8, C9, and C4.
- 3) Check the feedback networks, specifically:
  - a) Check C15 and R14.
  - b) Check C13 and R39.

## **Section 9 APPENDICES**

---

### **Appendix A PARTS ORDERING**

Please provide the Model numbers of the units involved when ordering genuine CARVER replacement parts. Also provide the CARVER part number and the generic part number to confirm the correct part needed.

The Carver Parts Department is open Monday thru Friday, 7:00 a.m. to 4:45 p.m. PST.

The following phone number is to be used for part orders only!

Technical assistance is not available on this line.

**1-800-433-0547**

Or if you prefer to FAX in your part order, please use the following FAX number:

**1-206-775-9180**

From time to time, when it is necessary, we may make a substitution for the original part ordered, due to circuit revisions or part availability.

Random deviation from the original CARVER designated part is not recommended!

Complete PCB replacement is not recommended. You must have prior approval for warranty repair should PCB replacement be necessary.

### DESIGN HISTORY

#### **Engineering Change Orders for Model Silver Seven t Magnetic Field Power Amplifier**

Note: Revision levels for assemblies are different than revision levels for parts lists and schematic diagrams.

ECO#:1024	DATE:04/21/89	REV.E Final Assembly Parts List - Effective S/N 068
REASON FOR CHANGE:	Use correct resistor type.	
PROCEDURE:	Change R98 to 2.7 ohm 5W wire wound resistor.	
ECO#:1042	DATE:04/27/89	REV.B LED Prep Parts List REV.D Meter Board Parts List REV.F Final Assembly Parts List - Effective S/N 218
REASON FOR CHANGE:	To make power LED brighter; to avoid "bumping" RP1 out of calibration; to improve ground connection.	
PROCEDURE:	Change LED limiting resistor to 4.7k ohms. Remove set wheel from RP1. Use longer X-fmr mounting screws. Add star washer to power supply grounding screw on Regulator board.	
ECO#:1044-1	DATE:05/09/89	REV.B Button-Up Parts List REV.A3 Meter Board REV.B Meter Schematic - Effective S/N 200
REASON FOR CHANGE:	To accomodate new style meter.	
PROCEDURE:	Use new meter plate. On meter board, delete jumper and R16; change C5 and R11; add C6 and R12.	
ECO#:1111-1	DATE:06/26/91	REV.C Button-Up Parts List - Effective S/N 368
REASON FOR CHANGE:	To adjust the height of the meter plate.	
PROCEDURE:	Use two meter plates glued together to increase height.	
ECO#:1149	DATE:07/13/89	REV.I Final Assembly Parts List - Effective S/N 808
REASON FOR CHANGE:	To improve the reliability of the triac.	
PROCEDURE:	Change to a 35A 600V triac.	
ECO#:1168	DATE:07/11/89	REV.D Button-Up Parts List - Effective S/N 408
REASON FOR CHANGE:	To improve the height of the meter plate.	
PROCEDURE:	Use one meter plate and attach with double-sided foam tape.	
ECO#:1256	DATE:10/13/89	REV.F Button-Up Parts List - Effective S/N 1100
REASON FOR CHANGE:	To improve cap bracket mounting; to improve chassis to signal ground.	
PROCEDURE:	Use 9/16" screws for mounting cap bracket. Use a kephnut on the power supply grounding screw on Power Supply board.	

ECO#:1267 DATE:10/17/89 REV.G Button-Up Parts List - Effective S/N 1765  
REASON FOR CHANGE: To meet safety agency approval.  
PROCEDURE: Replace MDQ12 fuse with MDA12 fuse.

ECO#:1272 DATE:10/24/89 REV.B Amp Schematic - Effective S/N 1581  
REASON FOR CHANGE: To make damping adjustable.  
PROCEDURE: Remove R9 and replace with 2K Trim Pot (RP2).

### **Engineering Change Orders for Model Silver Nine t Magnetic Field Power Amplifier**

ECO#:1734 DATE:05/22/91 REV.K Final Assembly Parts List  
Effective S/N 91614600001  
REASON FOR CHANGE: Improve adherence of feet.  
PROCEDURE: Use Loctite Depend Adhesive and Activator.

ECO#:1748 DATE:06/07/91 REV.L Final Assembly Parts List  
Effective S/N 91614600001  
REASON FOR CHANGE: Improve strength of shoulder washer.  
PROCEDURE: Use a nylon shoulder washer on Q6, Q14, Q16.

## Appendix D

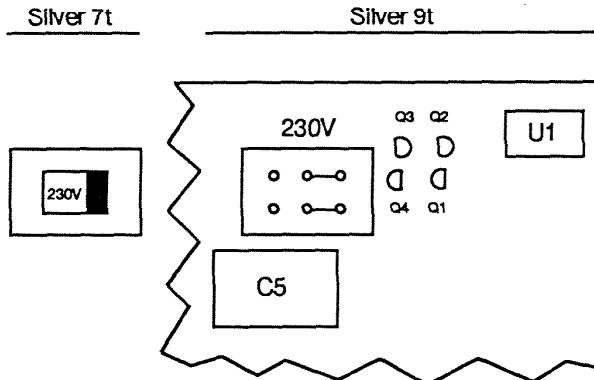

### VOLTAGE CONVERSION FOR SILVER 7t/SILVER 9t

#### Bill of Materials

Qty	Part Number	Description
1	315-13004-00	Fuse MDA 6-1/4A
1	315-13002-00	Fuse MDA 12A
1	530-10106-00	Label 6A SLO-BLO
1	530-10107-00	Label 220-240V

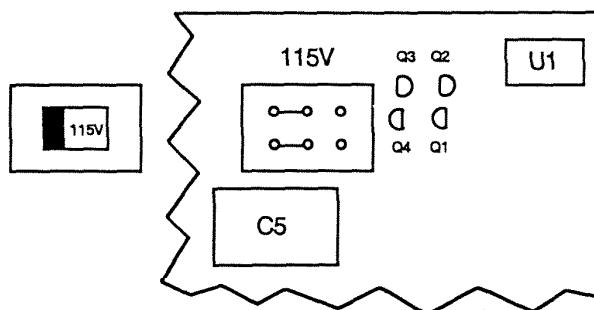

#### Directions for Change (115V to 230V)

1. For Silver 7t: Set the switch on the power supply regulator board to the 230V position.  
For Silver 9t: Move jumpers to 230V position.
2. Replace the MDA 12A fuse with an MDA 6-1/4A fuse (P/N 315-13004-00).
3. Attach the 6A SLO-BLO fuse label (530-10106-00) over the MDA 12 printing near the fuseholder.
4. Attach the 220-240V label over the 120 VOLTS printing near the line cord.

#### Directions for Change (220V to 115V)

1. For Silver 7t: Set the switch on the power supply regulator board to the 115V position.  
For Silver 9t: Move jumpers to the 115V position.
2. Replace the MDA 6-1/4A fuse with an MDA 12A fuse (P/N 315-13002-00).
3. Remove the 6A SLO-BLO fuse label near the fuseholder.
4. Remove the 220-240V label near the line cord.

---

## **Appendix E**

### **SERVICE BULLETINS**

Please insert Carver Service Bulletins pertaining to the Silver 7t or Silver 9t here to ensure proper repair in the future.

**CARVER CORPORATION  
SERVICE BULLETIN**

Service Bulletin # SST-1A	Model SST	Serial # Below 0218
---------------------------	-----------	---------------------

Reason: If the customer complains that the power L.E.D. is too dim, follow this procedure.

Procedure: 1. Replace 10k ohm resistor with 4.7k ohm resistor which is wired in series with the power L.E.D.

Delete: Qty-1 251-00094-03 (10k ohm 1/4 watt)	Add: Qty-1 251-00086-00 (4.7k ohm 1/4 watt)
--	--

SERVICE APPROVAL  
ENGINEERING APPROVAL

*Wade Reynolds* 6/2/89  
*Tom Richardson* 6-20-89

# CARVER CORPORATION SERVICE BULLETIN

Service Bulletin # SST-3A	Model: SST	Serial nos. A11
REASON: To eliminate damping pot drift.		Date: 7/26/90

DELETE	ADD
Qty 2 259-20010-00 2k Pot (RP2)	Qty 2 259-30001-00 500 ohm Pot (RP2) Qty 2 251-00067-00 750 ohm 1/4W resistor (R9) <i>FOR SILVER TH USE only 1 EA</i>

## PROCEDURE

On the amp board, replace RP2 with a 500 ohm pot.

On the foil side of the board, cut trace between RP2 and U2 pin 3.  
(See Figure 1A).

Solder R9, 750 ohm 1/4W resistor, between RP2 and U2 pin 3.  
(See Figure 1B).

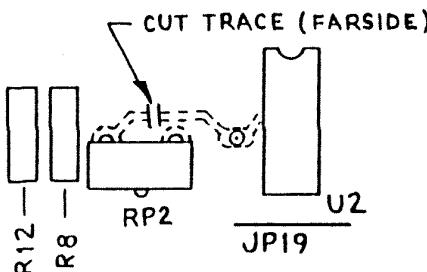

Figure 1A

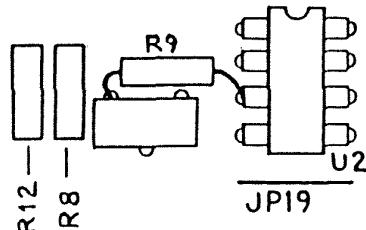

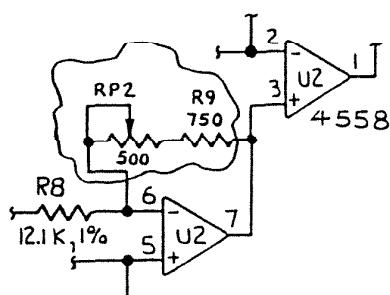

Figure 1B

Note: Adjust RP2 for a Gain of 29dB from input to output, with an 8 ohm load.

Engineering approval Vic P. Johnson 1-8-91

Service approval

# CARVER CORPORATION

## SERVICE BULLETIN

Service Bulletin # SST-4	Model: Silver Seven t	Serial nos. As needed
ASON:		Date: 1/29/91

If customer complains of hum or noise in the outputs.

DELETE	ADD
--------	-----

### PROCEDURE

1. Check continuity of input jack ground from the sleeve of the jack to chassis. In the assembly process, a thread locking glue is applied to the threads of the input jack. Occasionally, heat will cause the glue to migrate and insulate the ground lug on the input jack from the sleeve of the jack.

Note that the input jack is isolated from the chassis with a nylon washer. Connection to ground is made on the power supply board.

To repair:

- a) Tighten nut on input jack, or if this fails,
- b) Remove input jack and thoroughly clean the threads and ground lug before re-installing.

2. Tighten screw holding the bracket on the right rear side of the power supply board. This provides the connection between power supply ground and chassis ground, and it is important for this electro-mechanical connection to be reliable.

Engineering approval Vic Pappas 1-29-91  
Date approval B. Coker
