The amplifying stage basic structure is actually the one commonly used until now, this is, a push-pull mounted A-B class amplifier, using P-type (IRFP9240) and N-type (IRFP240) mosfets.

The system's controlling core is a NE5534 OpAmp, which is internally compensated in order to obtain an amplifying gain ratio equal or greater than 3. The amplifier's feedback runs through a resistor and a capacitor associated to the OpAmp's non-inverting input.

Transistors BF871 and BF872 are common-base configured, becoming actually a current source structure. They accomplish a dual function: on one hand, they polarise the mosfet's gate-source junction, keeping them on their conduction knee. On the other hand, they carry out the OpAmp's output voltage variations, referred to signal ground.

The polarisation current adjustment is fixed by a 2k5 trimming potentiometer connected to the BF transistors base. This current is added to the current source's output, which passes through the BF-transistors load resistors. The bias current stability against temperature is fixed through the BD437 transistors. Their temperature- dependent base emitter voltage curve is used to alter adequately the current source's reference voltage. As a consequence, if the temperature rises, the reference voltage decreases, thus the gate-source voltage also does, and finally the bias current also decreases.

The Zobel network, formed by a resistor-inductor-capacitor group, and which is located at the amplifier's output, intends to keep the amplifier's load impedance as constant as possible, no matter which load is connected to the stage's output, or which signal frequency is to be amplified, in order to prevent an inverted-phase feedback signal.

In order to avoid a DC offset on the output signal, a diac-triac tandem system is used, which shorts the output to signal ground when the DC level is enough to get the diac triggered. To prevent this from happening while carrying audio signal (sine-wave, music), the diac's reference voltage is taken from a filter formed by resistor R149 and capacitor C124.

The protection circuitry supervises at any time the power consumed by the MOSFETS. The circuitry basically consists on two sections: MOSFET's drain current (I_d) monitoring and drain-source voltage (V_{ds}) monitoring.

When the drain current exceeds a certain limiting value, a transistor (called control-transistor) becomes conducting, together with an auxiliary circuitry (helper), formed by a transistor (which is the same type as the control-transistor) and a 8'2V Zener diode. This value determines the point where the auxillary circuitry starts to run. The helper-transistor's base-emitter junction curve is used to obtain a non-linear variation on the MOSFETS gate-source voltage control, and thus on their drain current.

Moreover, as the helper-transistor's base-emitter current is temperature-dependent, the controlling circuitry (basically the control-transistor) compensates the safe operation area (SOA) drift due to temperature.

If the MOSFET's drain-source voltage (V_{ds}) drops too low, a second circuitry actuates to alter the control-transistor's triggering level, obtaining a SOA-like curve section and a current stage, which can be adjusted adequately in order to maintain the MOSFET's power consumption as close as possible to its SOA.

Moreover, the amplifier also includes an ANTICLIP system.

When the amplifier reaches its clipping level, the OpAmp becomes unable to keep the system under control, and as a consequence $\pm V$ peaks appear at its output (15V power supply). These peaks are used to be rectified and sent to an optocoupler (led-resistor) which modifies its impedance as a function of those peaks' amplitude. The resulting impedance is part of a voltage divider, together with the amplifier's input impedance. So, as the optocoupler increases its impedance, the amplifier's input signal level decreases until the system becomes stable.

Also a dual-function temperature control circuitry is provided:

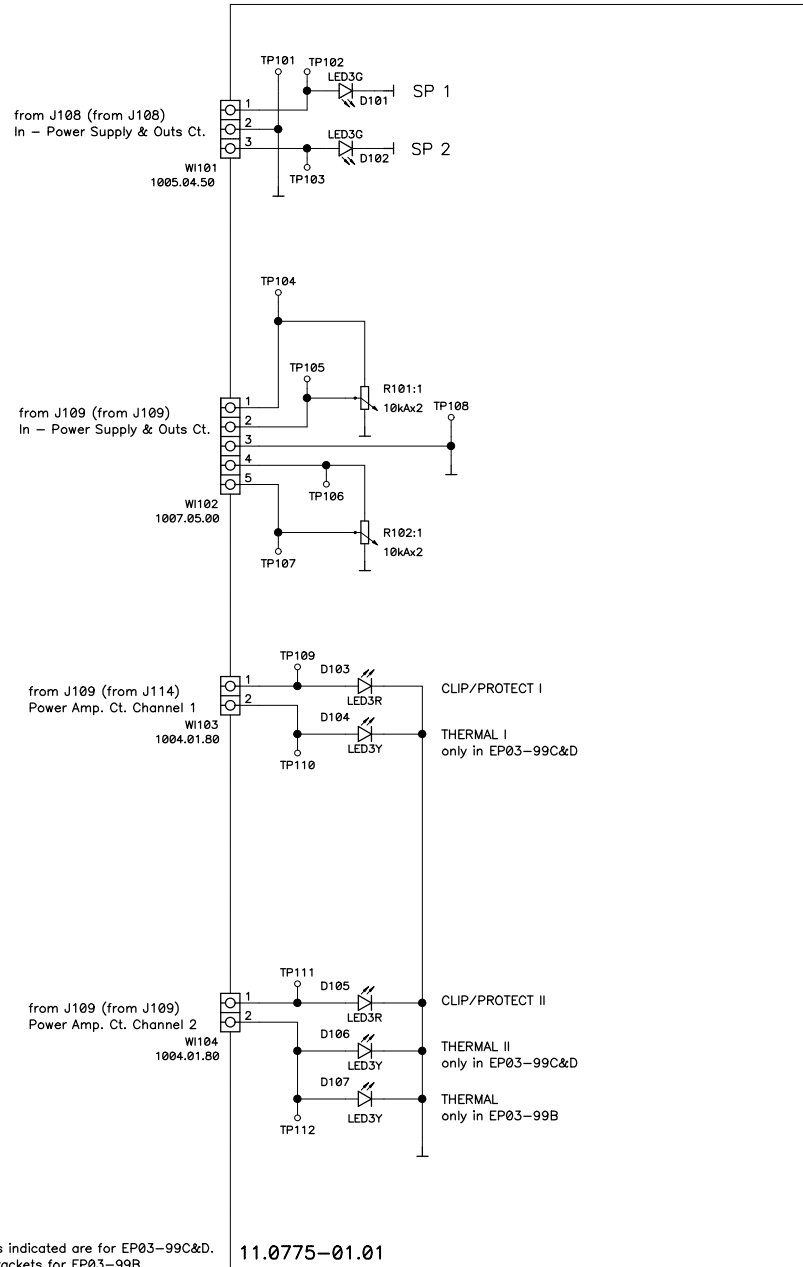

- Temperature-depending control of the cooling fan speed, whose voltage supply is variable between 7 and 14 Vac.
- Amplifier shutdown when temperature exceeds approximately 90°C.

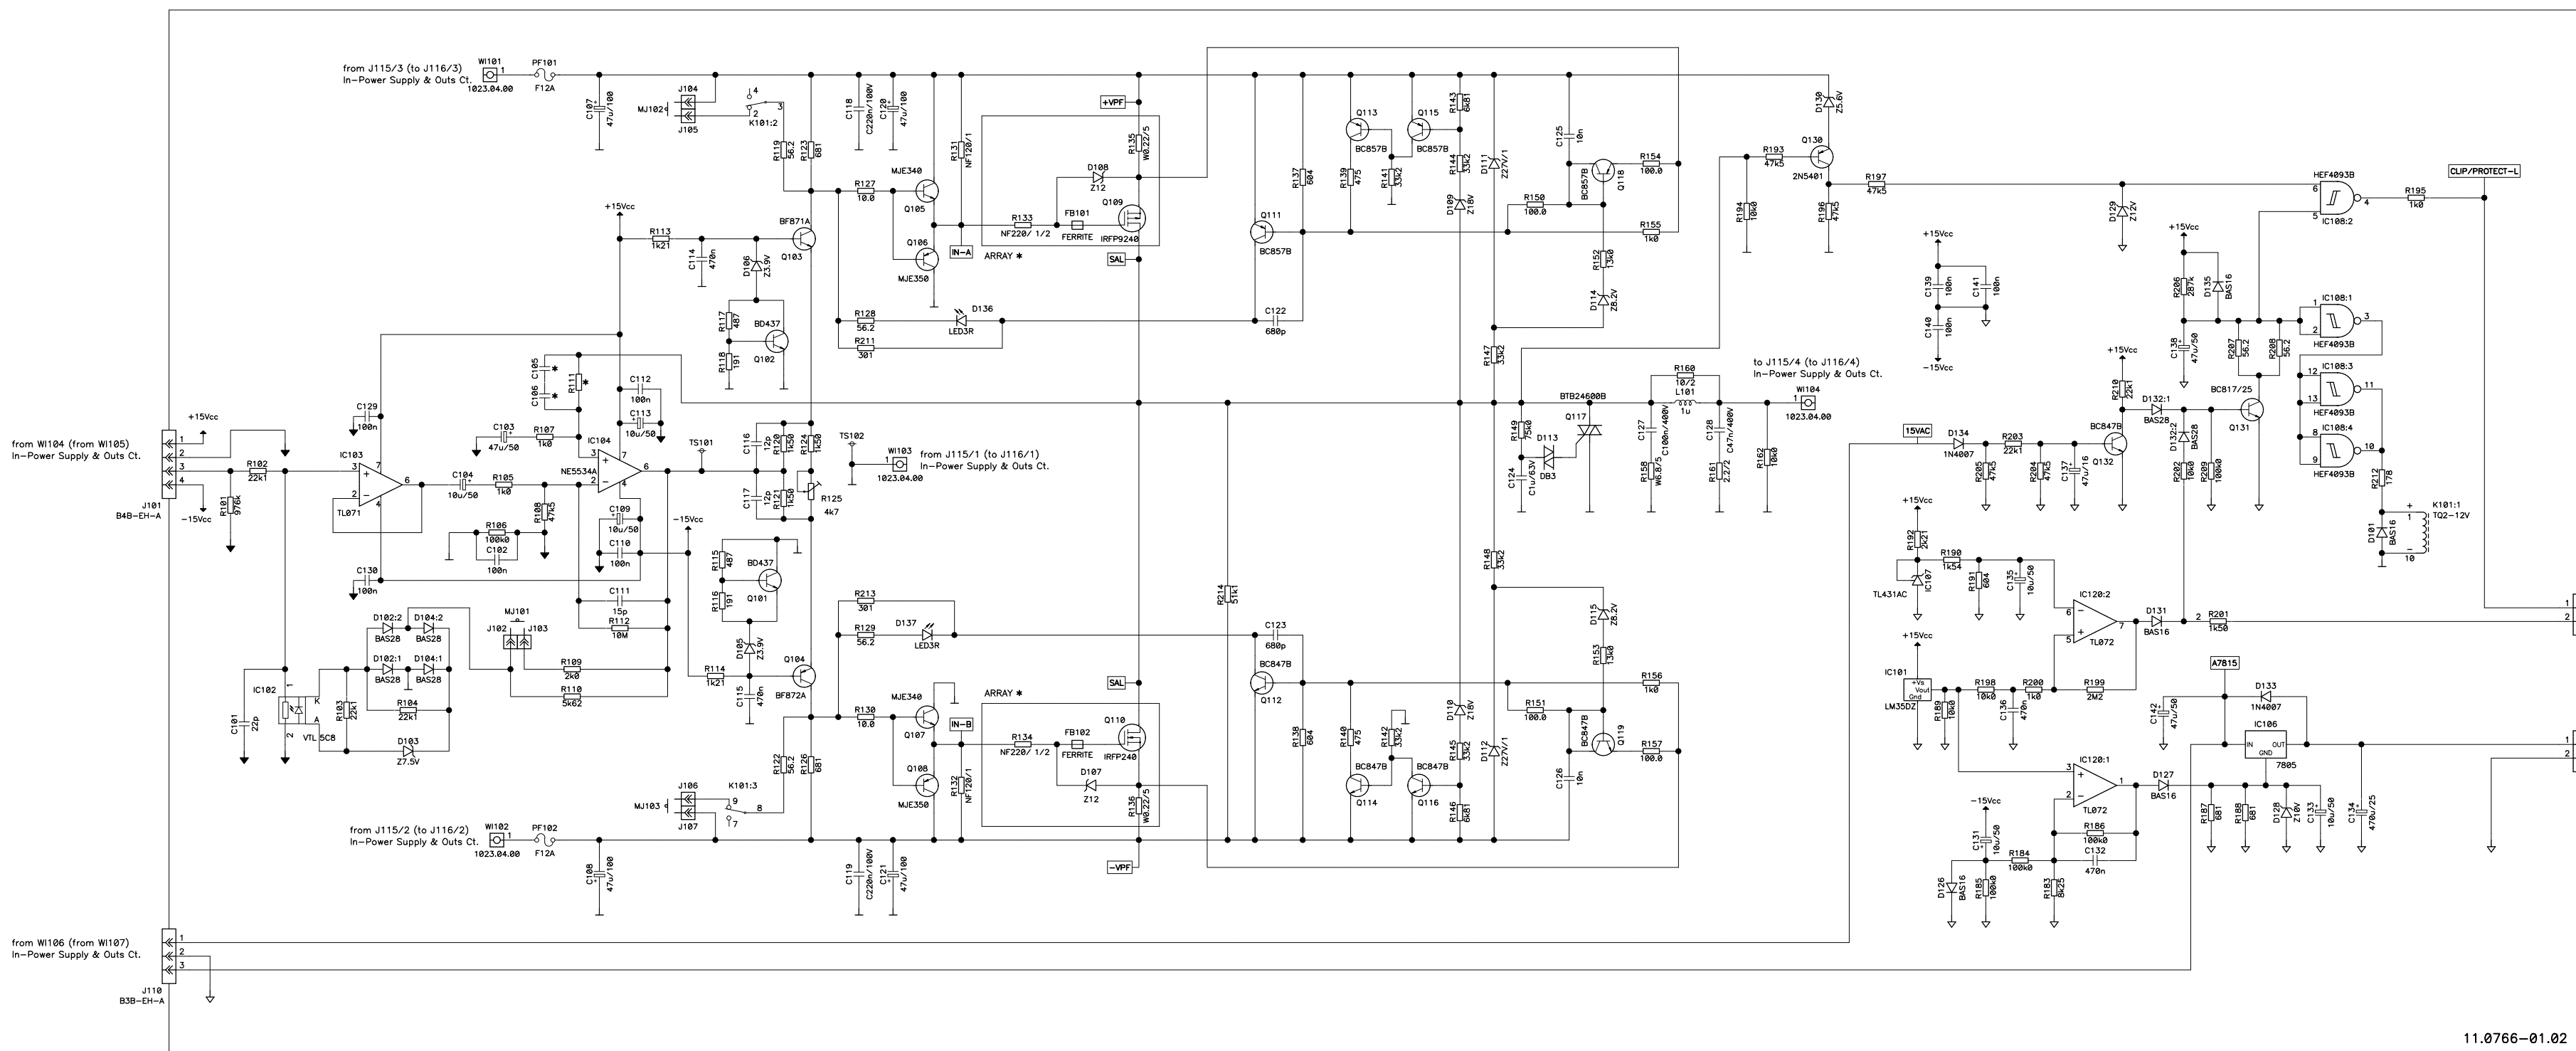

The circuitry is formed by LM35D-type IC, which acts like a thermal probe, an amplifier, thermal probe level comparator and a 7805-type voltage regulator.

The amplifier is responsible for the cooling fan speed control. The comparator triggers a relay, which cuts off the MOSFETs' bias current by shunting a 22W resistance to the BF-type transistors' load resistors. This way, the output signal of the amplifier is effectively cutted off.

The STAND-BY circuit.

This circuit keeps the safety relay closed for about 10 seconds, thus the MOSFET's bias current is cutted off during this period, until the whole system reaches again a voltage-stable situation. Due to this, hearing annoying transients and noises during start up through the loudspeakers is avoided. This delay is obtained by a RC-cell, where $R = 287K$, and $C = 47\mu F/50V$. During start up, this RC-cell's voltage smoothly rises until the 40106-type Trigger-Schmitt triggering level is reached, and the amplifier starts functioning. $C = 47\mu F$ resets or discharges when the unit is turned off. During a short period of time, a BC817-type transistor acts like a switch, connecting two 75W parallel resistors to $C = 47\mu/50V$.

Announcement addressed to Technical Support Services

Involved series:

APA1400 / APA1000 / APA600
PAM1100 / PAM2100
MPA4-80 / MPA6-80 / MPA4-150

VOLUME potentiometer replacement.

Replaced service part code: FCPR210040

When this potentiometer is being replaced, after soldering it on the printed circuit board, the two leads should be shorted as shown in the picture, in order to ensure a correct performance depending on the available service part.

WI101 TO WI104	1023.04.00	FC0H023400

PRELIMINAR:

- Set the MONO-STEREO switch to STEREO.
- Check the GROUND-LINK switch.
- Place a mini-jumper at connector J123's terminals (power supply).
- Select the subsonic filter switch to OFF.
- Verify that the correct cables and connections are used.
- Connect the unit's mains power cable to a variac output, and leave it on the 0V output voltage position.
- Keep an ammeter prepared to verify the unit's current demand.

VERIFICATION

- Turn on the unit without any load connected to its outputs by setting the main power switch to its ON position. Increase slowly the variac's output voltage until it reaches its maximum value, which is mains voltage. At this point, verify that the unit's bias current demand keeps its factory adjusted value and, if not, proceed to readjust this parameter. After this, fix the adjustment devices with sealing lacquer. Also check that the Power On led is lit.
- Replace the ammeter by the corresponding fuse. Warning! The power supply will be charged! Note: to discharge the power supply, apply a 0dB 2KHz input signal to the unit and turn its mains voltage down to 0V by reducing the variac's output voltage.
- Turn off the unit and afterwards on again in order to verify the time it remains in STAND-BY mode, which should last approximately 10 seconds. Also verify that when the unit is turned on, the cooling fans run up until their maximum speed.
- Verify both XLR and JACK input terminals, also check the attenuation values by sweeping their potentiometers between -v and 0dB.
- Verify the amplifier's output power while connected to the mains power supply:

- APA1400	635W	51V on 4Ω	BIAS CURRENT = 300mA
- APA1000	440W	42V on 4Ω	BIAS CURRENT = 250mA
- APA600	275W	33V on 4Ω	BIAS CURRENT = 150mA

- Verify the ANTICLIP system is functioning correctly by increasing the input signal level up to values higher than 0dB. The output signal should be smoothly clipped. Verify that if a mini-jumper is placed at the test terminals (which are located near the VTL5C8 package), the ANTICLIP system switches on earlier, making the clipped signal appear even more smoothed. Check that the front panel CLIP leds are lit, and observe that, when the input signal is damped 1 or 2 dB, the CLIP indicator leds turn off. Do not retire the mini-jumper.
- While applying a 0.5V input signal, verify the unit's frequency response bandwidth, which should be linear between 20Hz and 20KHz. The output signal should appear

distortion- and noise-free. Verify that even if the input signal frequency rises up to 50KHz, the output signal level only decreases 1 or 2 dB, but no distortion is noticed.

- Verify the MONO operation mode. Apply a 1KHz 0'5V input signal and set the MONO STEREO selection switch to the MONO position. The output signals should now appear in phase opposition one referred to the other, and only the Channel1 input potentiometer is responding. Connect an 8Ω load impedance to the unit's actual active output terminals of both outputs and verify that the anticlip system switches on easily when needed. Set the amplifier back to the STEREO operation mode.

- Connect an output load impedance formed by a 4Ω resistor shunted to a 2μF capacitor, and apply a 1KHz square waveform input signal. Monitor the output signal through an oscilloscope, and increase the input signal level until the output starts clipping. On the flat sections of the sandcastle output waveform, only two or three little ringings should be detected.

- To verify the subsonic filter, apply a 20Hz input signal. When the subsonic filter is active, the output signal should decrease 6.5dB referred to the non-active filter output level.

- Verify the THERMAL protection. When the thermal probe 1 and 2 leads are shorted, check that the relay opens, the THERMAL indicator led lights on, the output signal is cutted off and the cooling fan increases its speed up to the maximum running speed.

PROTECTIONS

- Turn off the signal generator. Select a 1KHz output signal, set the amplitude range to 1V but leave the amplitude control knob down to its minimum position.

- Connect a 0'5 ohm load impedance to the amplifier's output.

- Turn on the signal generator, and slowly increase the amplifier's input signal amplitude, while watching that the unit's output voltage does not exceed its limiting value, depending on the type under test, as listed below:

	FIRST STAGE	SECOND STAGE
- APA1400	13Vpp	22Vpp
- APA1000	20Vpp	25Vpp
- APA600	15Vpp	18Vp

Note: the clipping signal should appear distortion- and ringing-free. The different stages are obtained by varying the amplifier's mains voltage through the variac's output.

QUALITY CONTROL

All mechanical parts should be visually revised, in order to detect scratches on the unit's painting; all screws should be on their place, correctly tight and unmarked. Check out the unit's general presentation.

BURNING (BURN-IN) TEST

Leave the tested unit connected to its correspondent voltage mains socket, applying input signal and connecting load impedances, and working at 3dB under its maximum output power level for at least 24 hours.

VERIFICATION USING MUSIC

Verify the unit's sound quality, which should be distortion- and noise-free. Also check that all potentiometers can run smoothly their whole sweep, without annoying noises and crisperings. At their minimum position, check that output signal is completely cutted off. To ensure that all electrical junctions are well-fixed, hit the tested unit against your working table, obviously without damaging its outer presentation. Verify also all inputs and outputs. At last, short-circuit the output terminals while carrying amplified signal, and verify that once short-circuit is removed, the amplifying stages still are working.

PRELIMINAR:

- Set the MONO-STEREO switch to STEREO.
- Check the GROUND-LINK switch.
- Place a mini-jumper at connector J123's terminals (power supply).
- Select the subsonic filter switch to OFF.
- Verify that the correct cables and connections are used.
- Connect the unit's mains power cable to a variac output, and leave it on the 0V output voltage position.
- Keep an ammeter prepared to verify the unit's current demand.

VERIFICATION

- Turn on the unit without any load connected to its outputs by setting the main power switch to its ON position. Increase slowly the variac's output voltage until it reaches its maximum value, which is 230Vac. At this point, verify that the unit's bias current demand keeps its factory adjusted value and, if not, proceed to readjust this parameter. After this, fix the adjustment devices with sealing lacquer. Also check that the Power On led is lit.
- Replace the ammeter by the corresponding fuse. Warning! The power supply will be charged! Note: to discharge the power supply, apply a 0dB 2KHz input signal to the unit and turn its mains voltage down to 0V by reducing the variac's output voltage.
- Turn off the unit and afterwards on again in order to verify the time it remains in STAND-BY mode, which should last approximately 10 seconds. Also verify that when the unit is turned on, the cooling fans run up until their maximum speed.
- Verify both XLR and JACK input terminals, also check the attenuation values by sweeping their potentiometers between -v and 0dB.
- Verify the amplifier's output power while connected to the mains power supply:

- APA1400	635W	51V on 4Ω
- APA1000	440W	42V on 4Ω
- APA600	275W	33V on 4Ω

- Verify the ANTICLIP system is functioning correctly by increasing the input signal level up to values higher than 0dB. The output signal should be smoothly clipped. Verify that if a mini-jumper is placed at the test terminals (which are located near the VTL5C8 package), the ANTICLIP system switches on earlier, making the clipped signal appear even more smoothed. Check that the front panel CLIP leds are lit, and observe that, when the input signal is damped 1 or 2 dB, the CLIP indicator leds turn off. Do not retire the mini-jumper.

TAWA 215

TAWA 112

PRELIMINARY:

- Connect the verifier's mains plug, the power *ON* indicator LED should light up.
- Connect TAWA 112 or TAWA 215 to the verifier through the 7-wired bus and both jack-type connectors (right R, left L).
- Release the HIGH-LOW switch.
- Connect the signal generator to the RCA-type input, and apply a 0dB level 150Hz input signal.
- Connect the millivoltmeter-oscilloscope set to the unit's RCA-type output.

VERIFICATION of TAWA 112

- HIGH-level outputs :
 - 150 Hz -6dB
 - 400 Hz -1dB
 - 1kHz -2dB
 - 10 kHz 2,5dB
 - 50 kHz 0dB
- LOW-level outputs :
 - Press and lock the HIGH-LOW pushbutton.
 - 20 Hz 0dB
 - 60 Hz 1dB
 - 75 Hz 2dB
 - 150 Hz -6dB
- Check that when the ST-MONO labelled pushbutton is pressed, the right-channel output signal is cutted off.

VERIFICATION of TAWA 215

- HIGH-level outputs :
 - 20 Hz 0,5dB
 - 50 Hz 2dB
 - 200 Hz -1dB
 - 1kHz -4dB
 - 10kHz 2dB
- LOW-level outputs :
 - Press and lock the HIGH-LOW pushbutton.
 - 20 Hz 0,5dB
 - 50 Hz 2dB
 - 150 Hz -6dB
- Check that when the ST-MONO labelled pushbutton is pressed, the right-channel output signal is cutted off.

- Note : To make the circuit's operation easier to understand, some frequency response curves from the described filters are enclosed.
