1. Specifications

Motor	: Coreless DC servomotor
Drive system	: Direct drive
Speeds	: 33-1/3 and 45 rpm
Speed detection	: Integrated frequency generator
Servo system	: Quartz-locked positive and negative servo control
Pitch control	: ± 6 Hz (reference: 440Hz)
Starting time	: Within 0.6 sec. (60°)
Wow and flutter	: Within 0.02% (WRMS)
S/N	: 65dB (IEC-B), 75dB (DIN-B)
Starting torque	: 1.2kg/cm
Speed deviation	: Within 0.002%
Load characteristics	: 0% (with a 120g total tracking force)
Drift	: 0.0004%H
Power characteristics	: 0% (± 10 V)
Temperature characteristics	: 0.00003%/ $^\circ$ C
Turntable platter	: 31cm aluminium diecast
Quick stop time	: Within 1 sec.
Power supply	: 120V AC
Power consumption	: 16W (50/60Hz)
Dimensions	: 15cm(H) x 35.8cm(W) x 35.8cm(D)
Weight	: 10kg (net)

2. Features

- **Quartz-locked turntable**

The oscillating frequency of an oscillator circuit using crystal quartz is accurate and stable, as suggested by the fact that quartz is used in clocks and watches. The quartz-locked turntable utilizes this accurate oscillating frequency to control the speed of the turntable. In both accuracy and stability, quartz-locked speed control is far superior to the conventional servo systems.

- **Coreless DC servomotor**

DC servomotor, in general, consume less power and produce higher torque than AC servomotors. But a disadvantage with DC servomotors is irregular rotation. This is because the stator is divided into several cores with coils wound thereon, forming several gaps which cause irregular torque in combination with the rotor. One way to avoid this irregular rotation is to use a turntable which rotates with a high-inertia flywheel effect. Another way is to modify the waveform of the current which is supplied to the coils.

But the TT-101 adopted the coreless stator to substantially avoid such irregular rotation problems. To avoid the deterioration of efficiency, a new structure was developed employing dual rotor magnets with the stator coil placed between them.

As a result of the new design, improved turntable specifications are obtained – S/N ratio: 65dB and wow and flutter: 0.02%(WRMS).

- **1Hz pitch control**

The pitch, "A'" is standardized at 440Hz according to international standards, and is the standard for all western musical instruments. In other words, the tuning of all instruments of the orchestra is based on this pitch. But in reality, the basic tuning pitch of each orchestra differs due to the instrumentation and individual characteristics of each orchestra, as well as the personality of the conductor. The diagram shows such differences by orchestra. Most of the pitches range within ± 6 Hz of 440Hz. To reproduce these subtly different pitches, a quality turntable with highly accurate rotation is required. Another important requirement is the possibility of minute speed adjustment. If the speed of a turntable could be adjusted to the individual pitch used by an orchestra while at the same time remaining controlled by a quartz-locked servo system, the benefits of flexibility and precision would be significant from a musicological viewpoint. For this reason the TT-101 is equipped with built-in speed-control facilities which can adjust the pitch in 1Hz steps within a range of ± 6 Hz of 440Hz. The difference of pitches between master tape recorders and disc record cutting machines has been intentionally ignored before but now the speed of a record can be adjusted to match the original pitch of the orchestra, even if the master was recorded differently from the original performance. For example, a performance of the NHK Symphony Orchestra on one record can be adjusted to match the pitch of the same performance on a record by the London Symphony Orchestra, for the enjoyment of a critical comparison.

The "A'" key of a piano in your home is usually tuned to 440Hz. When you practice the piano while playing back a record, you can adjust the pitch of the record, to be in perfect tune with your piano.

- **Digital speed indication**

The TT-101 designed to be one of the highest quality consumer grade turntables, incorporates a four figure digital counter (the circuit capacity is to five figures) to indicate the speed clearly and accurately. Because the TT-101 has a built-in measurement apparatus, it can be used by professionals in broadcast or recording studios, where utmost reliability is required.

Increasing the frequency from the frequency generator for the speed detection by 1,000 times makes the count time shorter and the count more effective. To measure the speed accurately, at least 1.8 seconds, which is the time required for one revolution of the turntable, is needed. The TT-101 count time is 2 seconds.

- **Start characteristic and speed indication**

The TT-101 has an excellent start characteristic. After having pushed one of the start buttons (33-1/3 or 45 speed changeover button) it takes 0.6 seconds (33-1/3 rpm), to reach standard speed. But digital indication appears 3.5 seconds after the start, for in order to indicate the rotation speed accurately, the count is delayed until after the start button is pushed and 2 seconds have passed. A RUN/HOLD switch for checking the speed is provided under the turntable. Put this switch in the RUN position, and the counter indicates from 0 to 33.33 (or from 0 to 45.00) continuously and repeatedly. When it is in HOLD, the counter indicates a fixed figure.

- **Positive and negative servo control**

Factors which disturb the servomotor such as wear of the rotating parts, increased load or voltage drop, usually act to slow down the turntable speed. To cope with this, the conventional servomotor increases the drive current to the drive circuit to accelerate the motor. However, to correct excess acceleration due to increased voltage or servo overshooting, it only switches off the drive current. This results in poor response because of the inertia of the rotating parts. The new positive and negative servo control is capable of correcting the speed in both directions. This also makes it possible to bring the speed instantly to a steady state when it is switched from 45 rpm to 33-1/3 rpm.

- **Quick stop**

With most turntables, it takes some time before the turntable stops completely after the stop button has been pressed, owing to inertia in the rotating parts. This makes changing records rather inconvenient. To solve this problem, the TT-101 is equipped with a quick stop device. When the stop button is pressed, an electronic brake produces a reverse-current in the drive circuit and instantly stops the rotation with reverse motor torque.

- **Integrated frequency generator**

A frequency generator for speed detection is an integral part of the motor. To detect the speed, a disc rotor has 180 grooves cut in its circumference and a doughnut-shaped magnet is attached to this disc rotor. Therefore, 180 magnetic fluxes are formed around this magnetic component, under which a stator coil for detection is printed on a doughnut-shaped circuit board. When the motor is rotating, 180 pulses per revolution are available from this circuit board.

- **Toroidal wound transformer**

The TT-101 is equipped with a toroidal wound transformer which is ten times more efficient than the EI core transformer. It is less vibrant, and has less flux leakage, so the S/N ratio has been greatly improved.

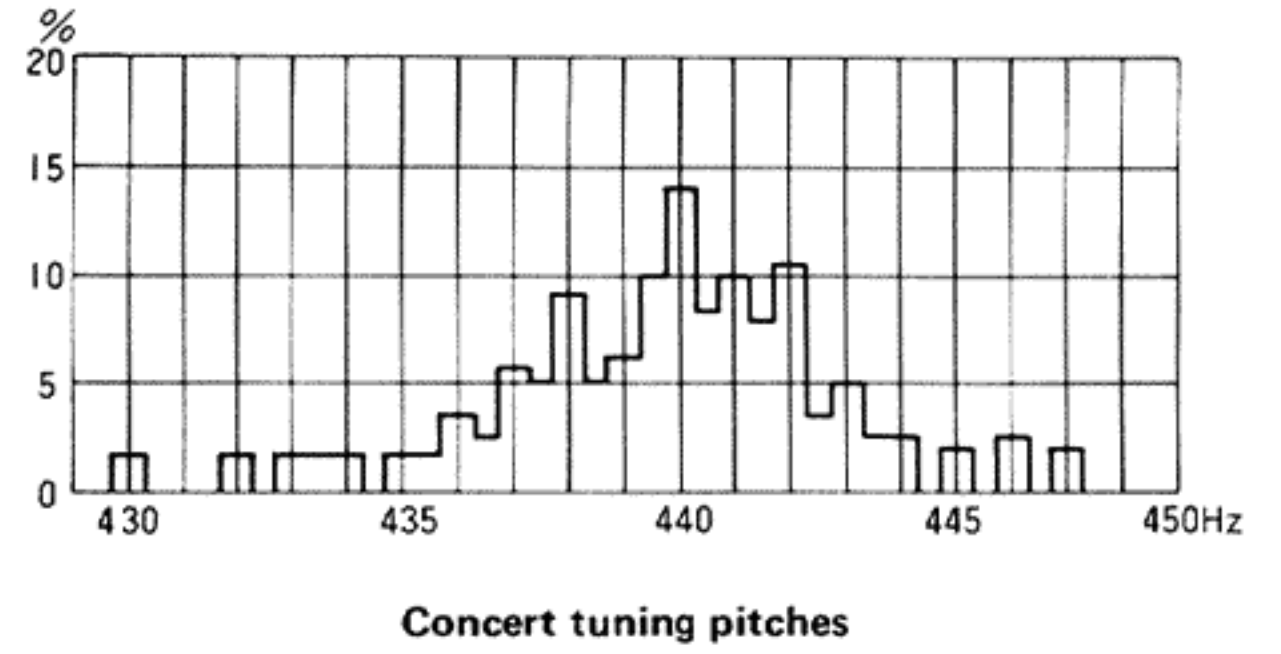

Fig. 1

3. New Technical Information

3-(1) Block Diagram

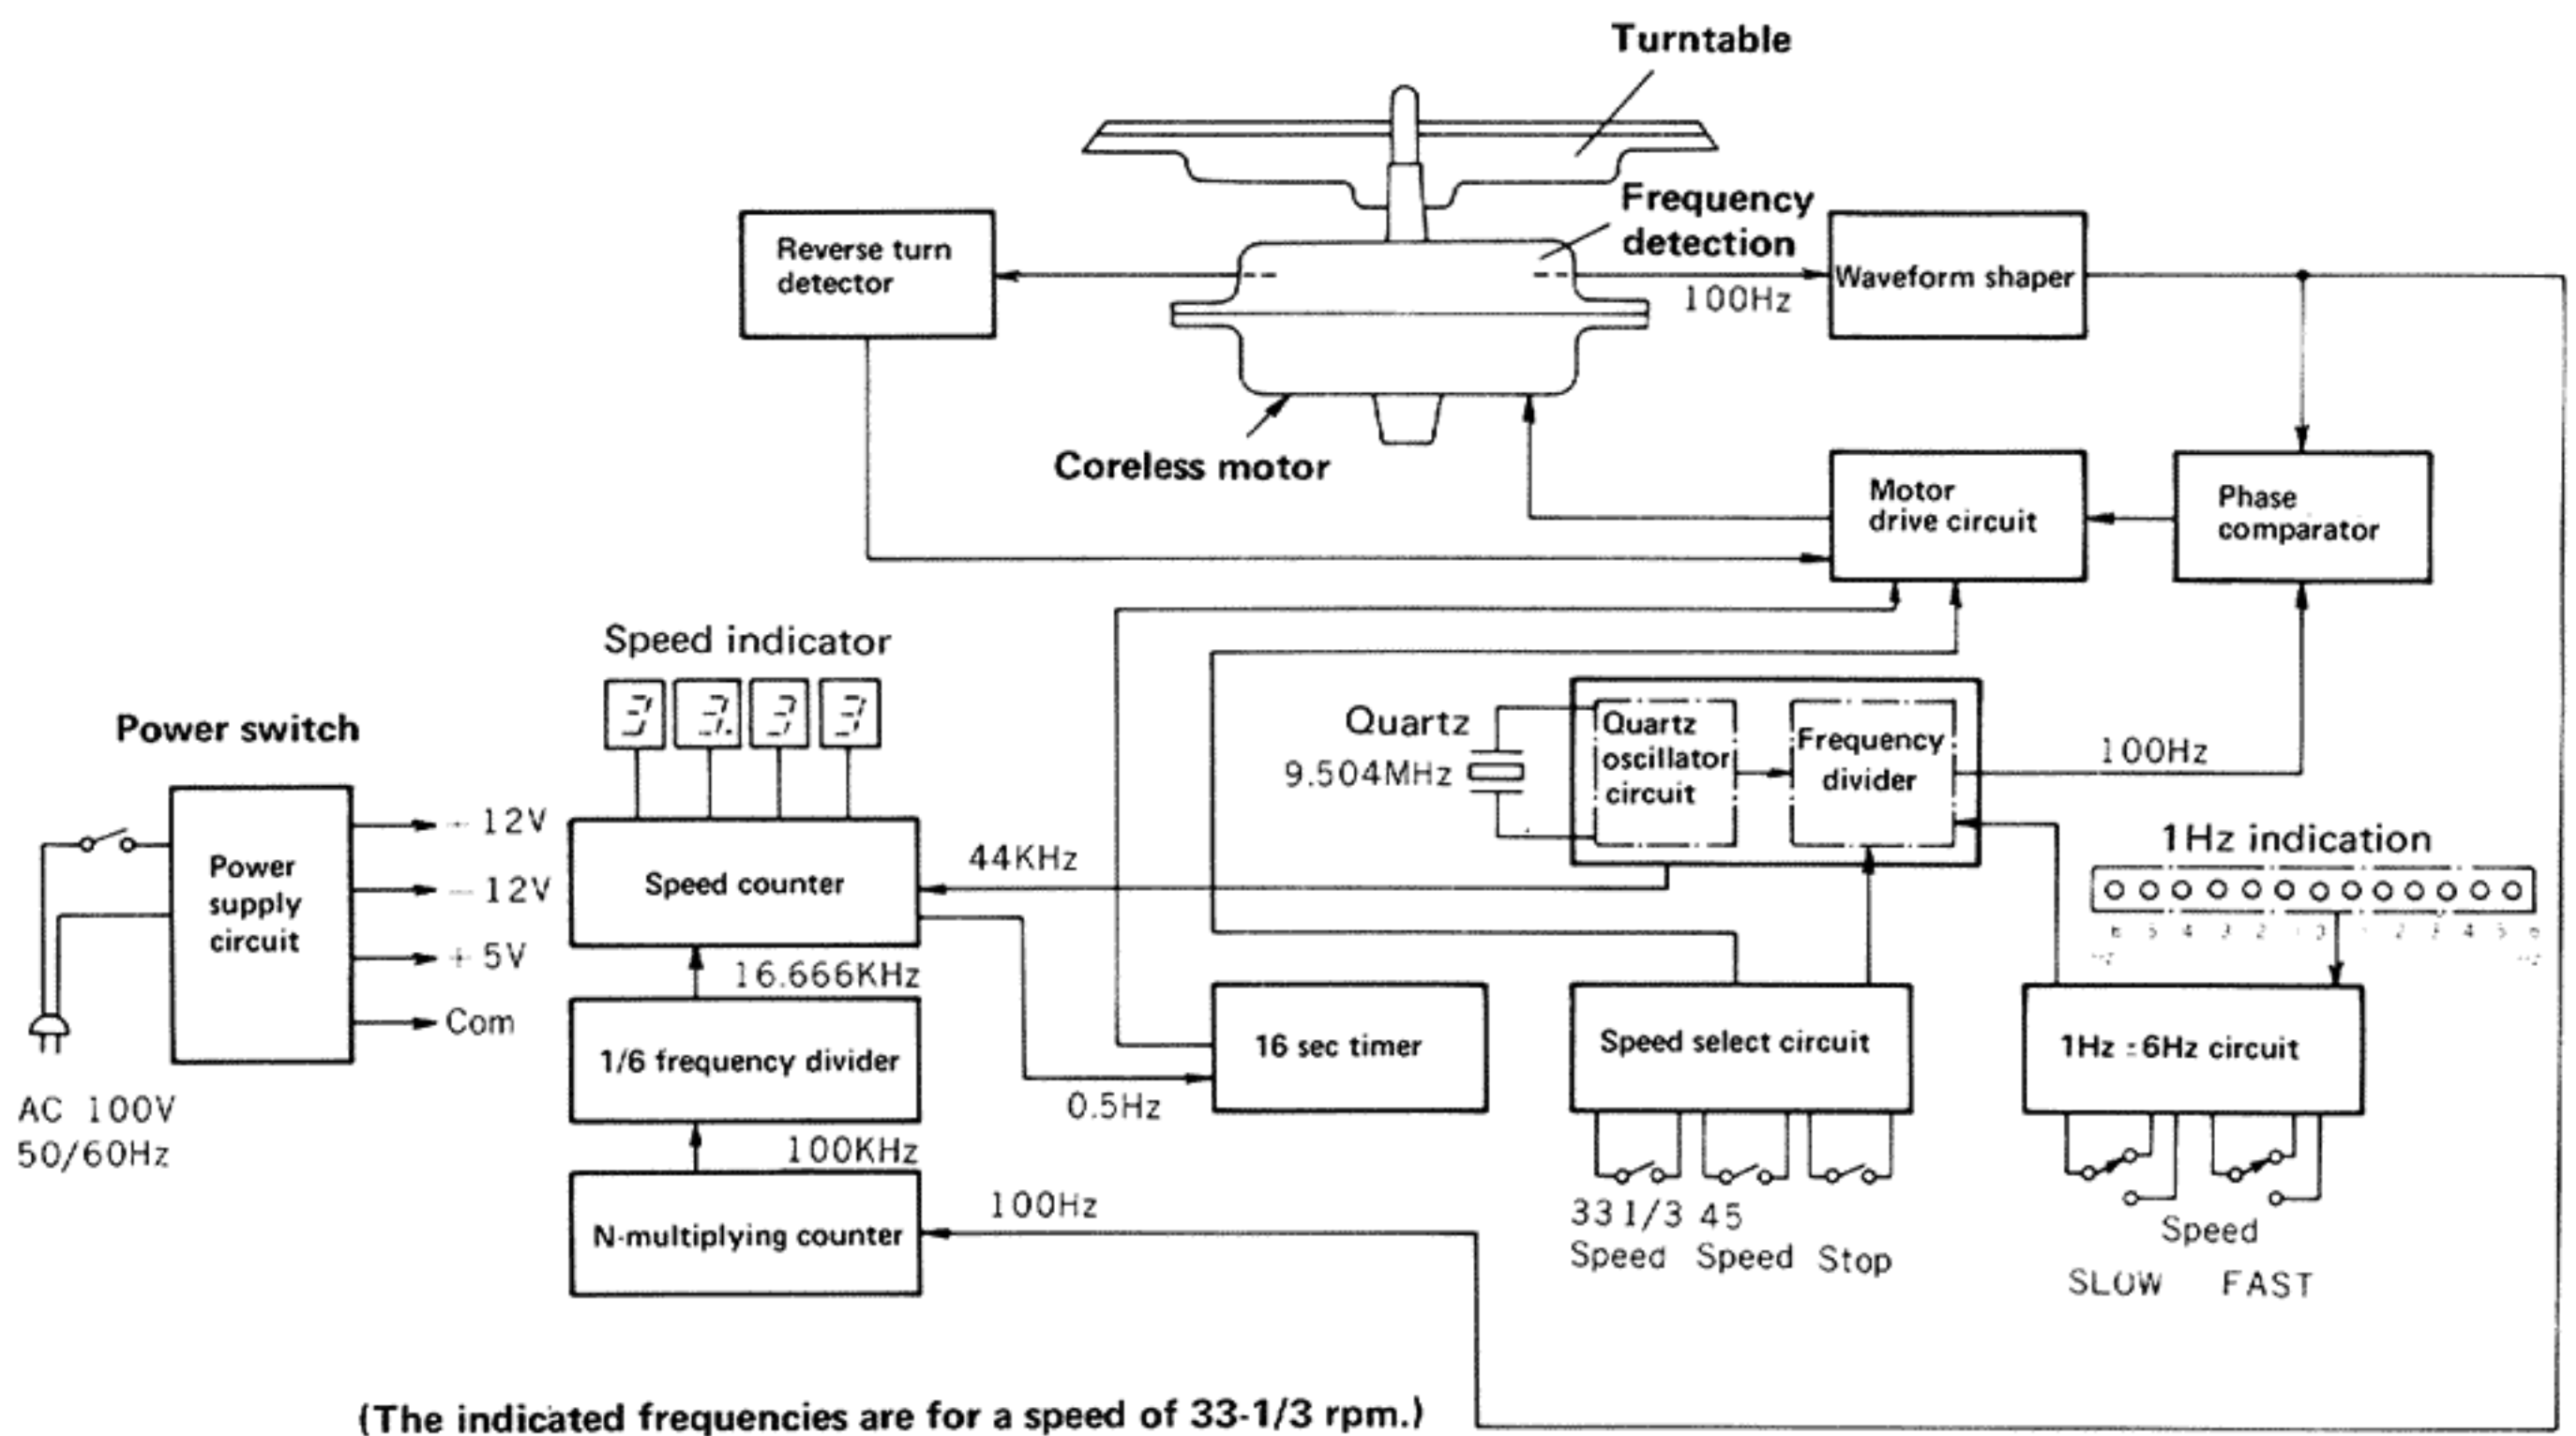

Fig. 2

3-(2) Crystal Oscillation Frequency Divider and 1 Hz Indication

1. C. MOS LSIT SC3042 consists of the elements shown in the block diagram of Figure 2.

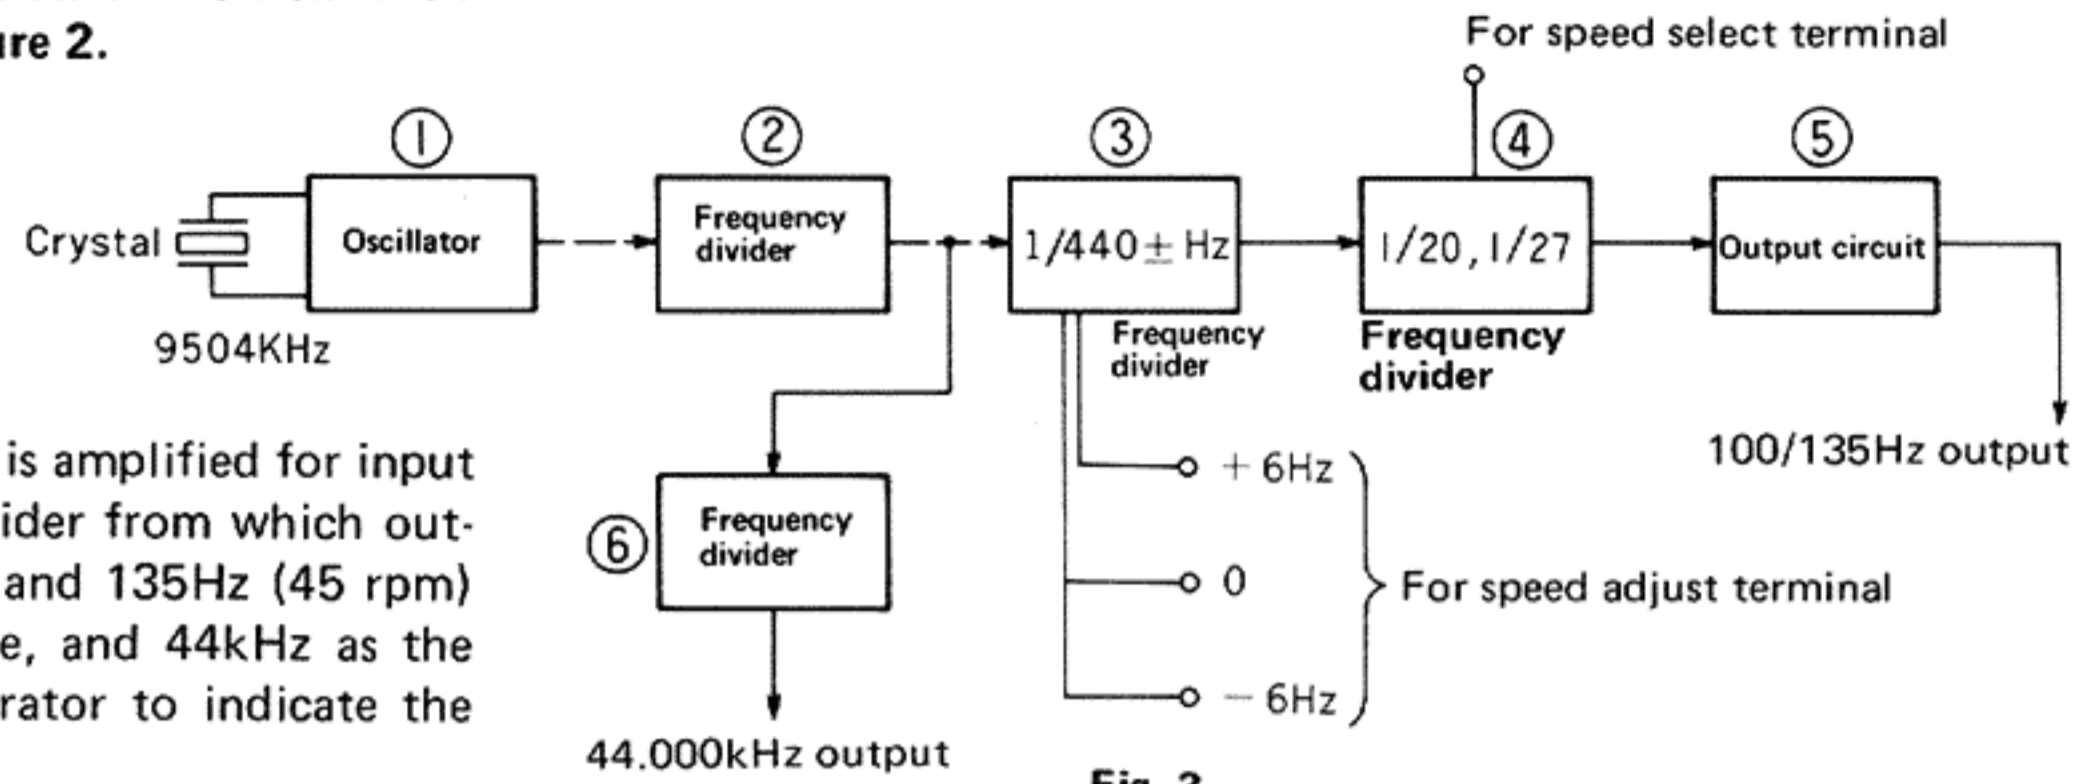

Fig. 3

- a. The crystal oscillator output is amplified for input to the built-in frequency divider from which outputs of 100Hz (33-1/3 rpm) and 135Hz (45 rpm) for the quartz-lock turntable, and 44kHz as the input to the time base generator to indicate the rated rpm.
- b. Selection terminals on frequency dividers 1/20 and 1/27 are connected to Vcc or Vss to permit output circuit 6 to produce minus pulses required in rpm selection.
- c. The grounded speed adjustment terminals permit adjustment in 1Hz increments within the 1/436 – 1/446 frequency division ratio.
- d. The divided frequency for the counter is not adjustable and is obtained by demultiplying 9504kHz, then further demultiplying the result in succeeding steps to obtain the time base.

The pin-connections are shown in Figure 4.

Fig. 4

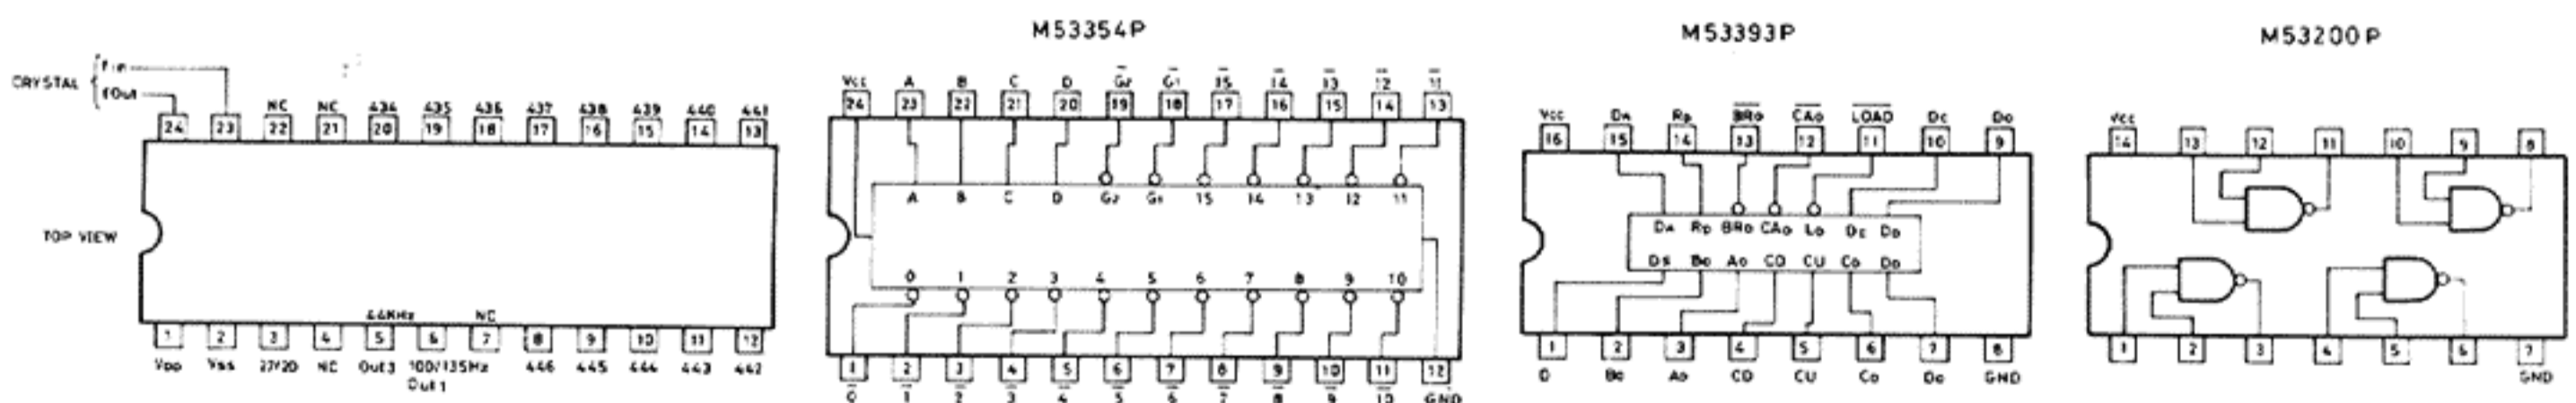

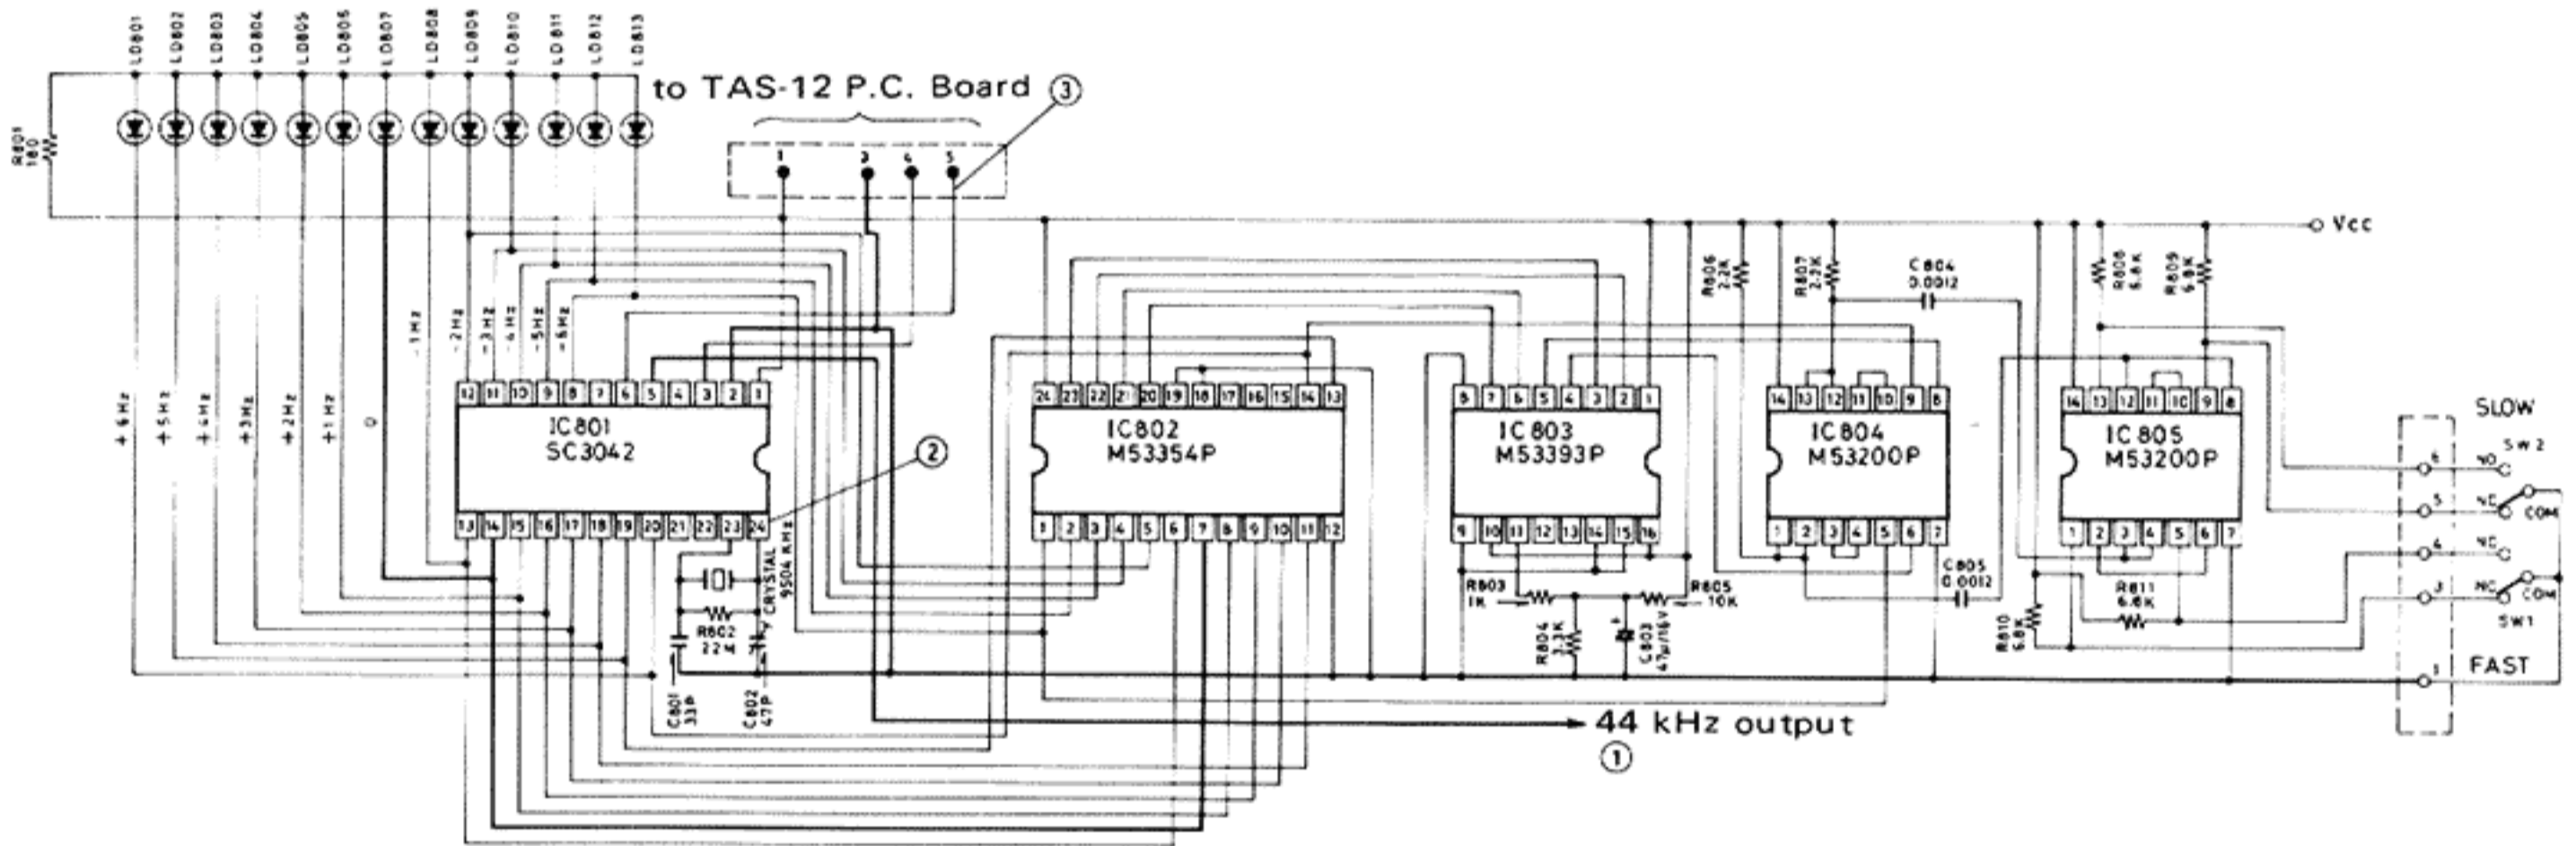

Fig. 5

Fig. 6

2. Indicator section

A. Circuit operation

- a. This section encodes and decodes the $\pm 6\text{Hz}$ adjustment, which results in a maximum $\pm 6\text{Hz}$ deviation from the basic $1/440$ demultiplication of a pulse input to permit indication by the indicator lamp. Push buttons are provided to cause two pulse generation circuits to generate SLOW and FAST pulses. Figure 4 shows the SLOW pulse generation circuit in which the output of IC805, consisting of two NAND circuits is latched to the first input pulse, thus holding it stable to succeeding noise generated by push-operation. Depression of the button yields an increment of deviation and releasing it enables the deviation to be set at that level. In addition, another pair of NAND circuits in IC804 receives a -6Hz clamp signal input from Pin (1) of M53354 to prevent pulse inputs also created by the push-button switch operation from producing outputs causing the deviation to proceed beyond -6Hz .

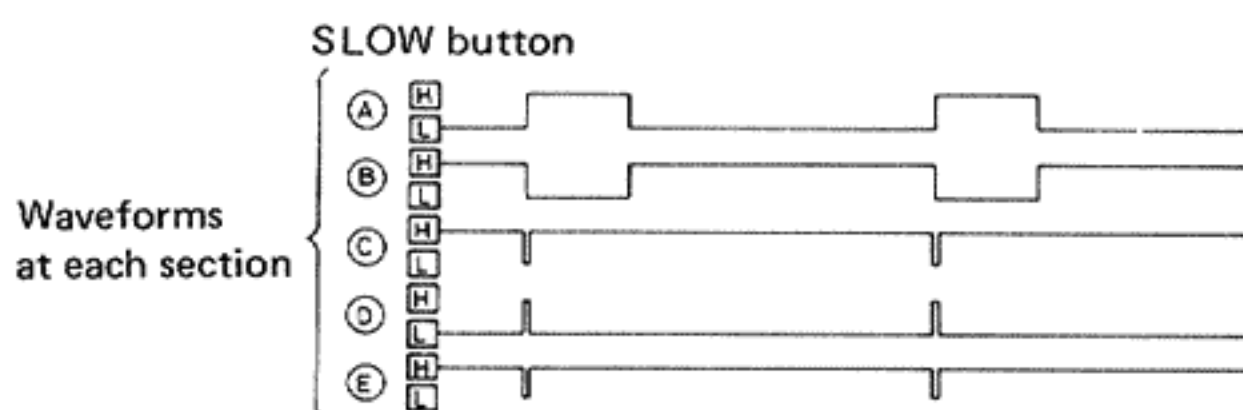

Fig. 7

- b. The FAST pulse generation circuit is identical to the SLOW circuit described in the above except for the pin connection.
- c. A SLOW or FAST pulse is generated when the pushbutton is depressed. However, holding the button depressed will not produce additional pulses. Succeeding pulses are generated only when the IC805 is reverse-latched by repressing the button.
- d. The NAND gate in IC804 and IC805 (physical No. M53200) has the input/output relationships shown in Figure 8. As is seen, when one of the two inputs is Low, the output is always High regardless of the High/Low states of the other input, thus making Low inputs predominant over High inputs.

Fig. 8

The NAND gate shown above is the basis for all other T.T.L IC's, and should be carefully studied and remembered.

B. Up-down counter

Adjustment can be set at the desired level by inputting accumulative SLOW or FAST pulses to hexadecimal counter M53393. The counter acting as an ordinary flip-flop IC has the capability of adding or subtracting the number of pulses depending on whether the inputs are count-up pulses or countdown pulses. Pin (4) M53393 is for count-down inputs and Pin (5) is for count-up inputs.

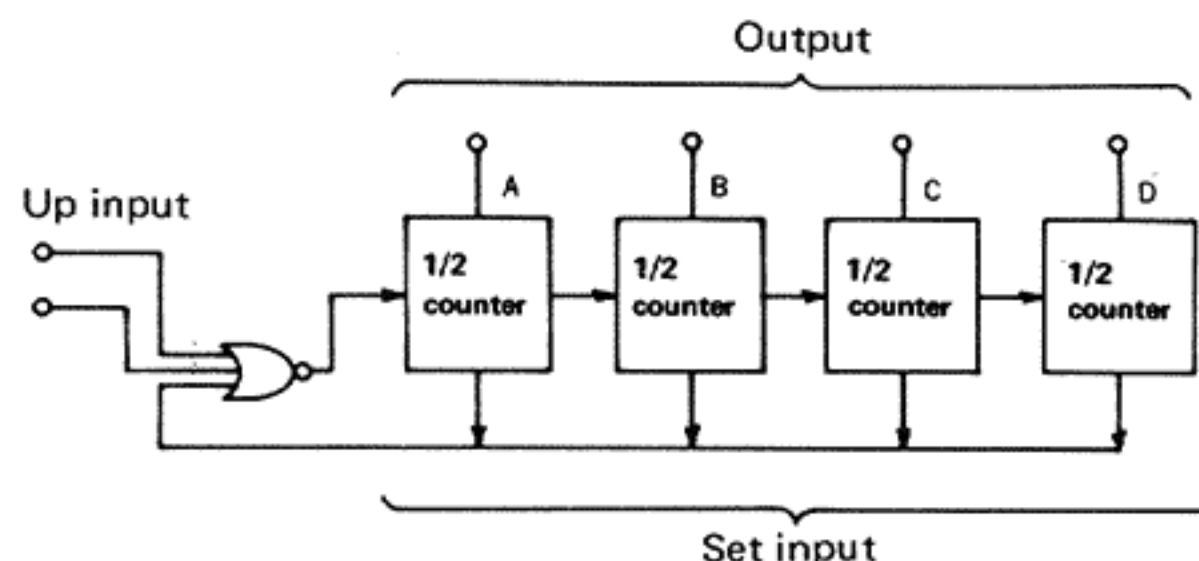

Fig. 9

M53393 consists of four $1/2$ counters having the capacity of counting a number within the range of 0 through 15, but is actually clamped by its input circuit within a range of 0 through 13.

If the set terminal of M53393 has been initialized, contents of the set input counter are output from terminals A, B, C and D.

Initializing M53393 is performed by grounding Pin (11). This permits use of the turntable, only when the power switch is turned on. The shape of the initialization signal is determined by the CR combination as shown in Figure 10.

When the power switch is turned on, the voltage between the ends of C803 ($47\mu\text{F}/16\text{V}$) becomes zero thus making Pin (11) Low and setting the initial value into the counter. The charge current to C803 through R805 ($10\text{k}\Omega$) then makes it High again thus disabling the initial set signal.

C. Indicator

IC802 M53394 is a 16-line decoder which decodes parallel input data of Binary Code Decimal outputs from M53393 to one of the 16 indicator outputs.

That is, a signal representing one of numbers 0 through 13 decoded from BCD makes a specific output terminal Low to light a corresponding light emitting diode and also for other purposes.

This equipment utilizes Low level outputs from IC802 as indicator signals for the SC3042 1Hz counter, while at the same time performing both deviation indication and varying the ratio of frequency division.

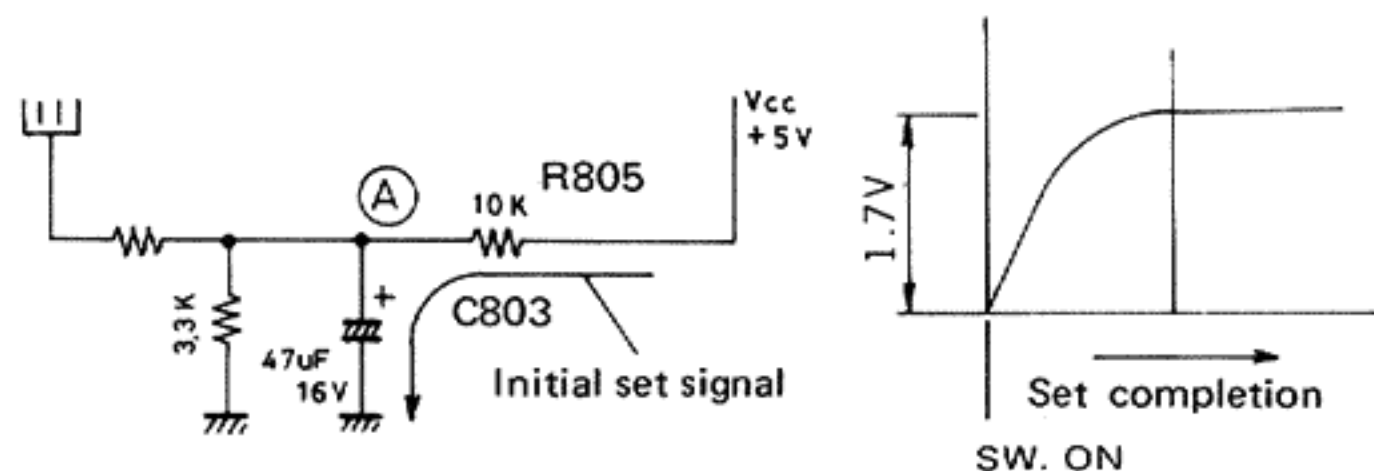

Fig. 10

3-(3) Time Base Generator Circuit

- The time base generator circuit generates 0.5Hz and 0.25Hz signals by frequency-dividing the 44kHz signal from IC801 (SC4042) through the count down process.
 - Count-down is accomplished by amplifying the output from SC3042 through buffer X801, and passing it to M53293 for 1/11 division. Though the IC was originally intended for dividing its input to 1/16, feed-back to X802 and X803 of the input to the counter causes Pin (2) and Pin (3) to be reset (if both Pins are High level, the contents of the counter become zero by the falling portion of the 11th input pulse, thus making the counter restart counting there). Since this circuit performs feed-back, the signal waveforms vary depending on the section from which they are obtained (refer to Figure 12).
- Three IC's, IC807, IC808 and IC809 are 1/10 decade counters each consisting of a 1/2 counter and a 1/5 counter thus yielding a total 1/1000 demultiplication. The M53293 of IC810 divides the 4Hz output from IC809 into 1/8 or 0.5Hz which is used as the basis of the reset signal. Further, the 4Hz output is also divided into 1/2 or 0.25Hz for use as the time base for counting the frequency of an external source input.
- Reset**
To determine the count-start point, all IC's from IC807 through IC810 are reset at one time to produce the 0.25Hz timing shown in Figure 11.

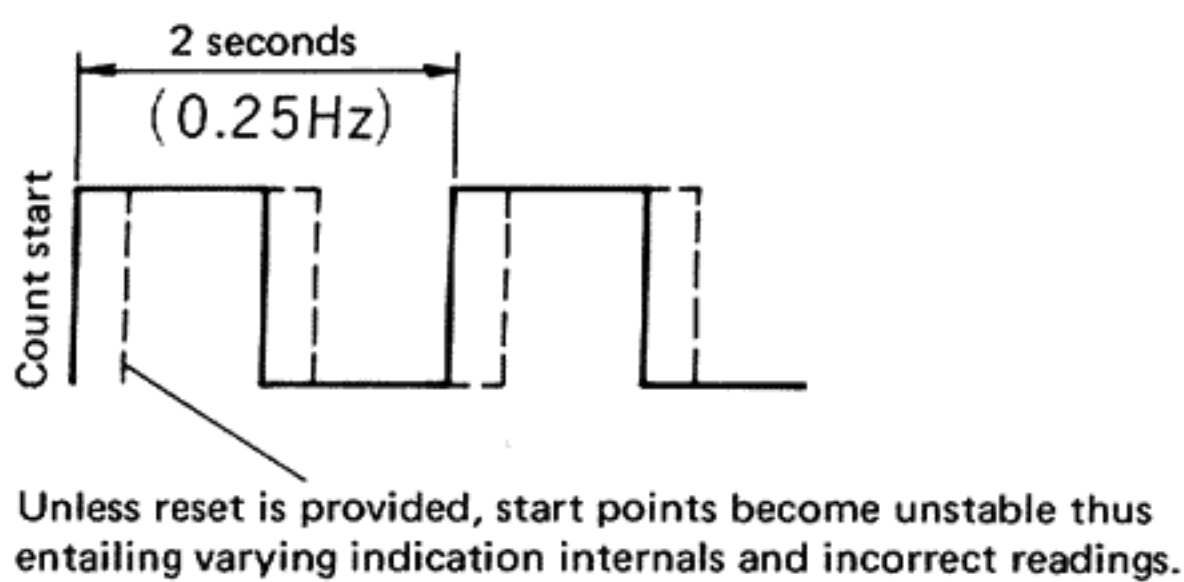

Fig. 11

- Waveform at each section**
To observe the process of frequency count down, utilize a dual beam or dual trace oscilloscope. A single beam oscilloscope may also be employed, and confirmation obtained by a frequency counter.
- Waveform**

Fig. 12

f. Time base generator circuit

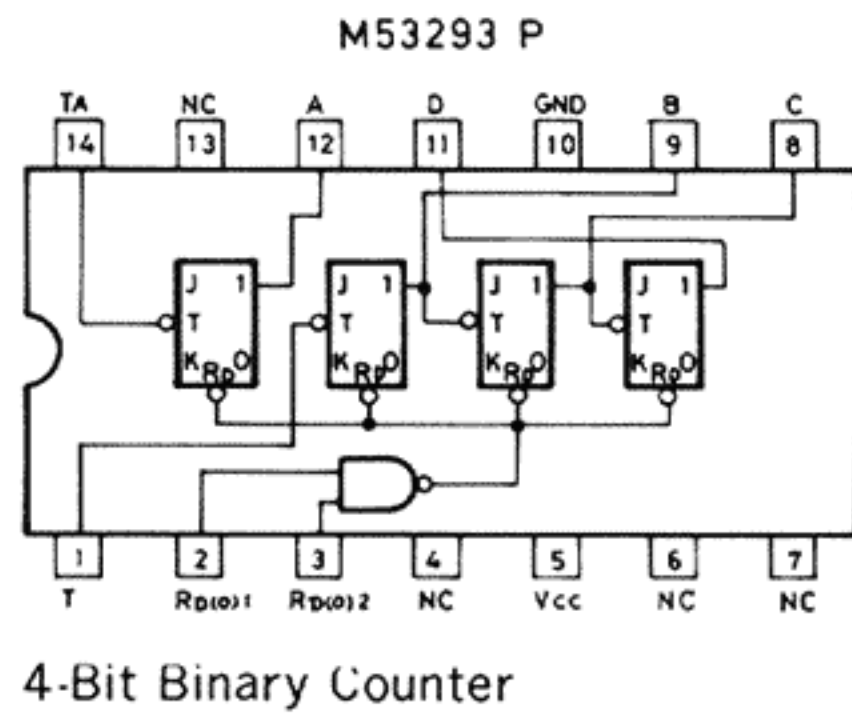

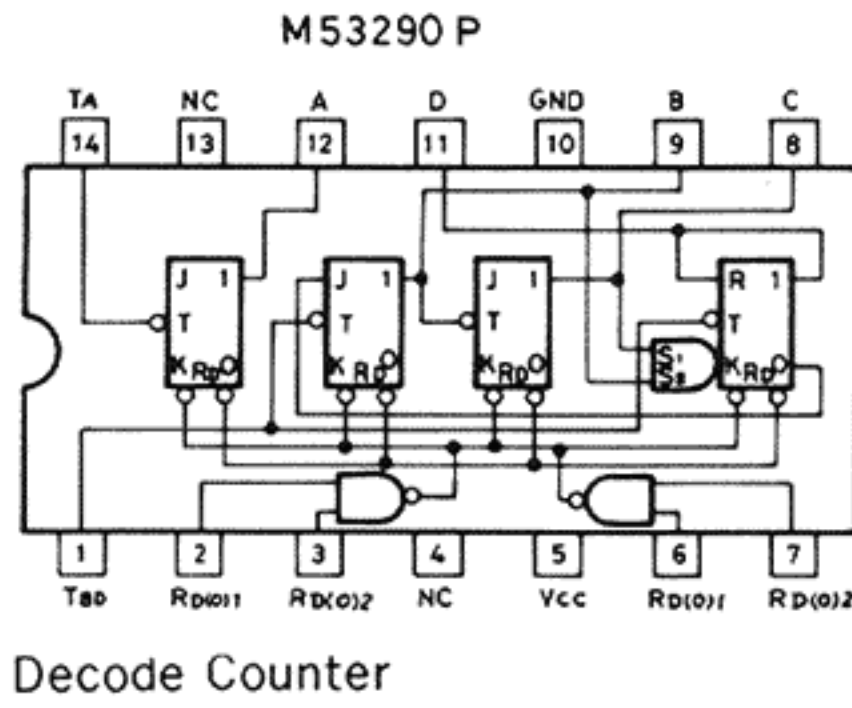

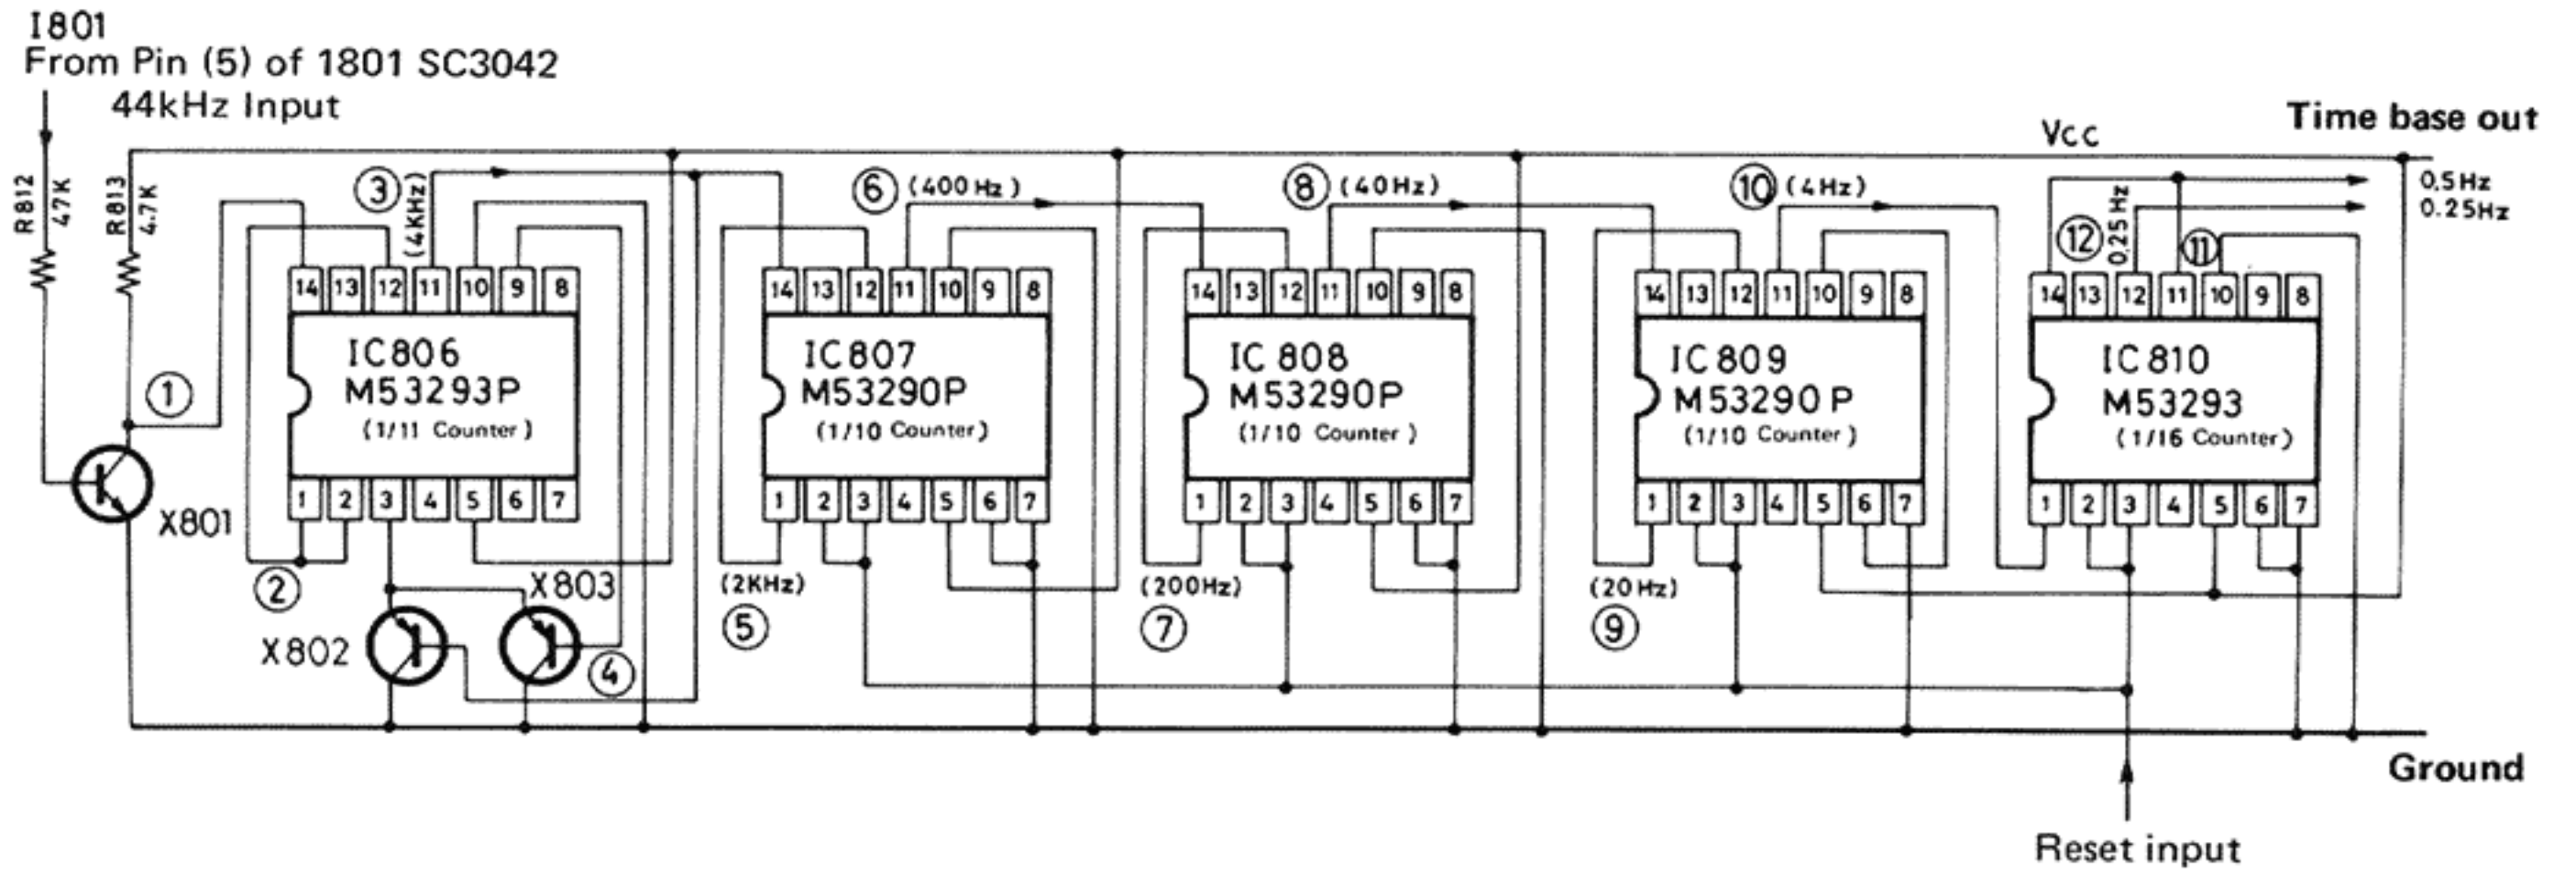

Fig. 13

3-(4) Count Circuit

Count Set Circuit

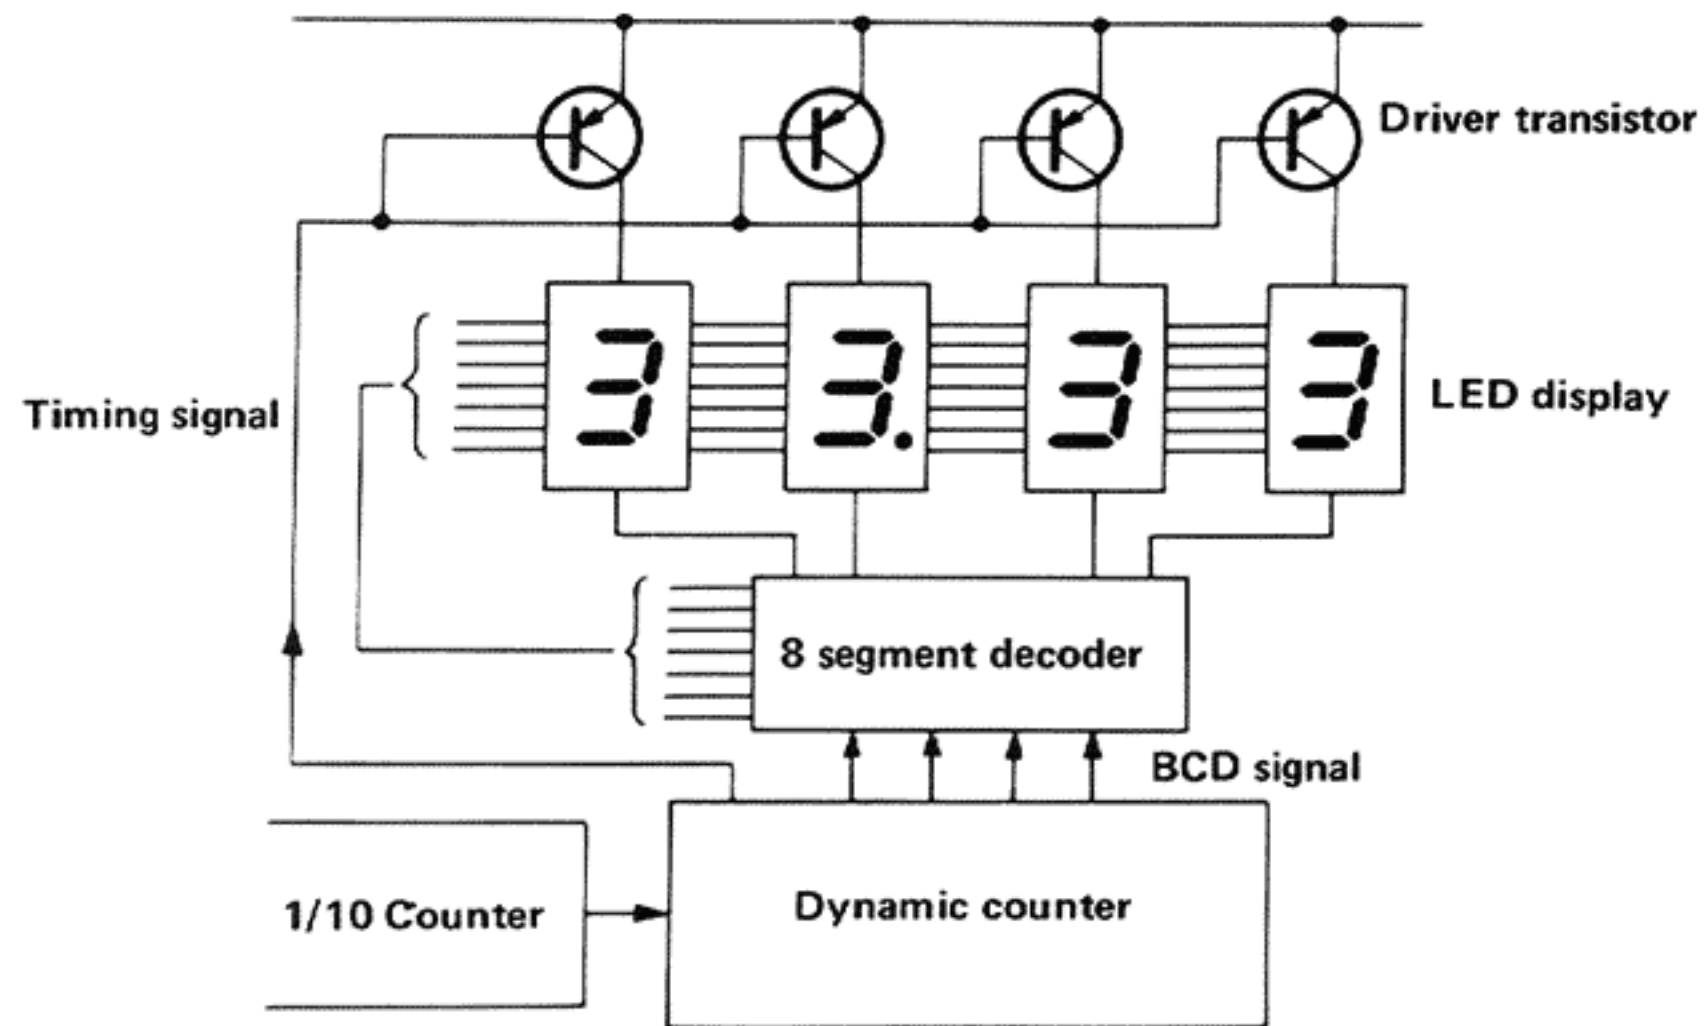

Fig. 14

Timing Chart of Count Circuit

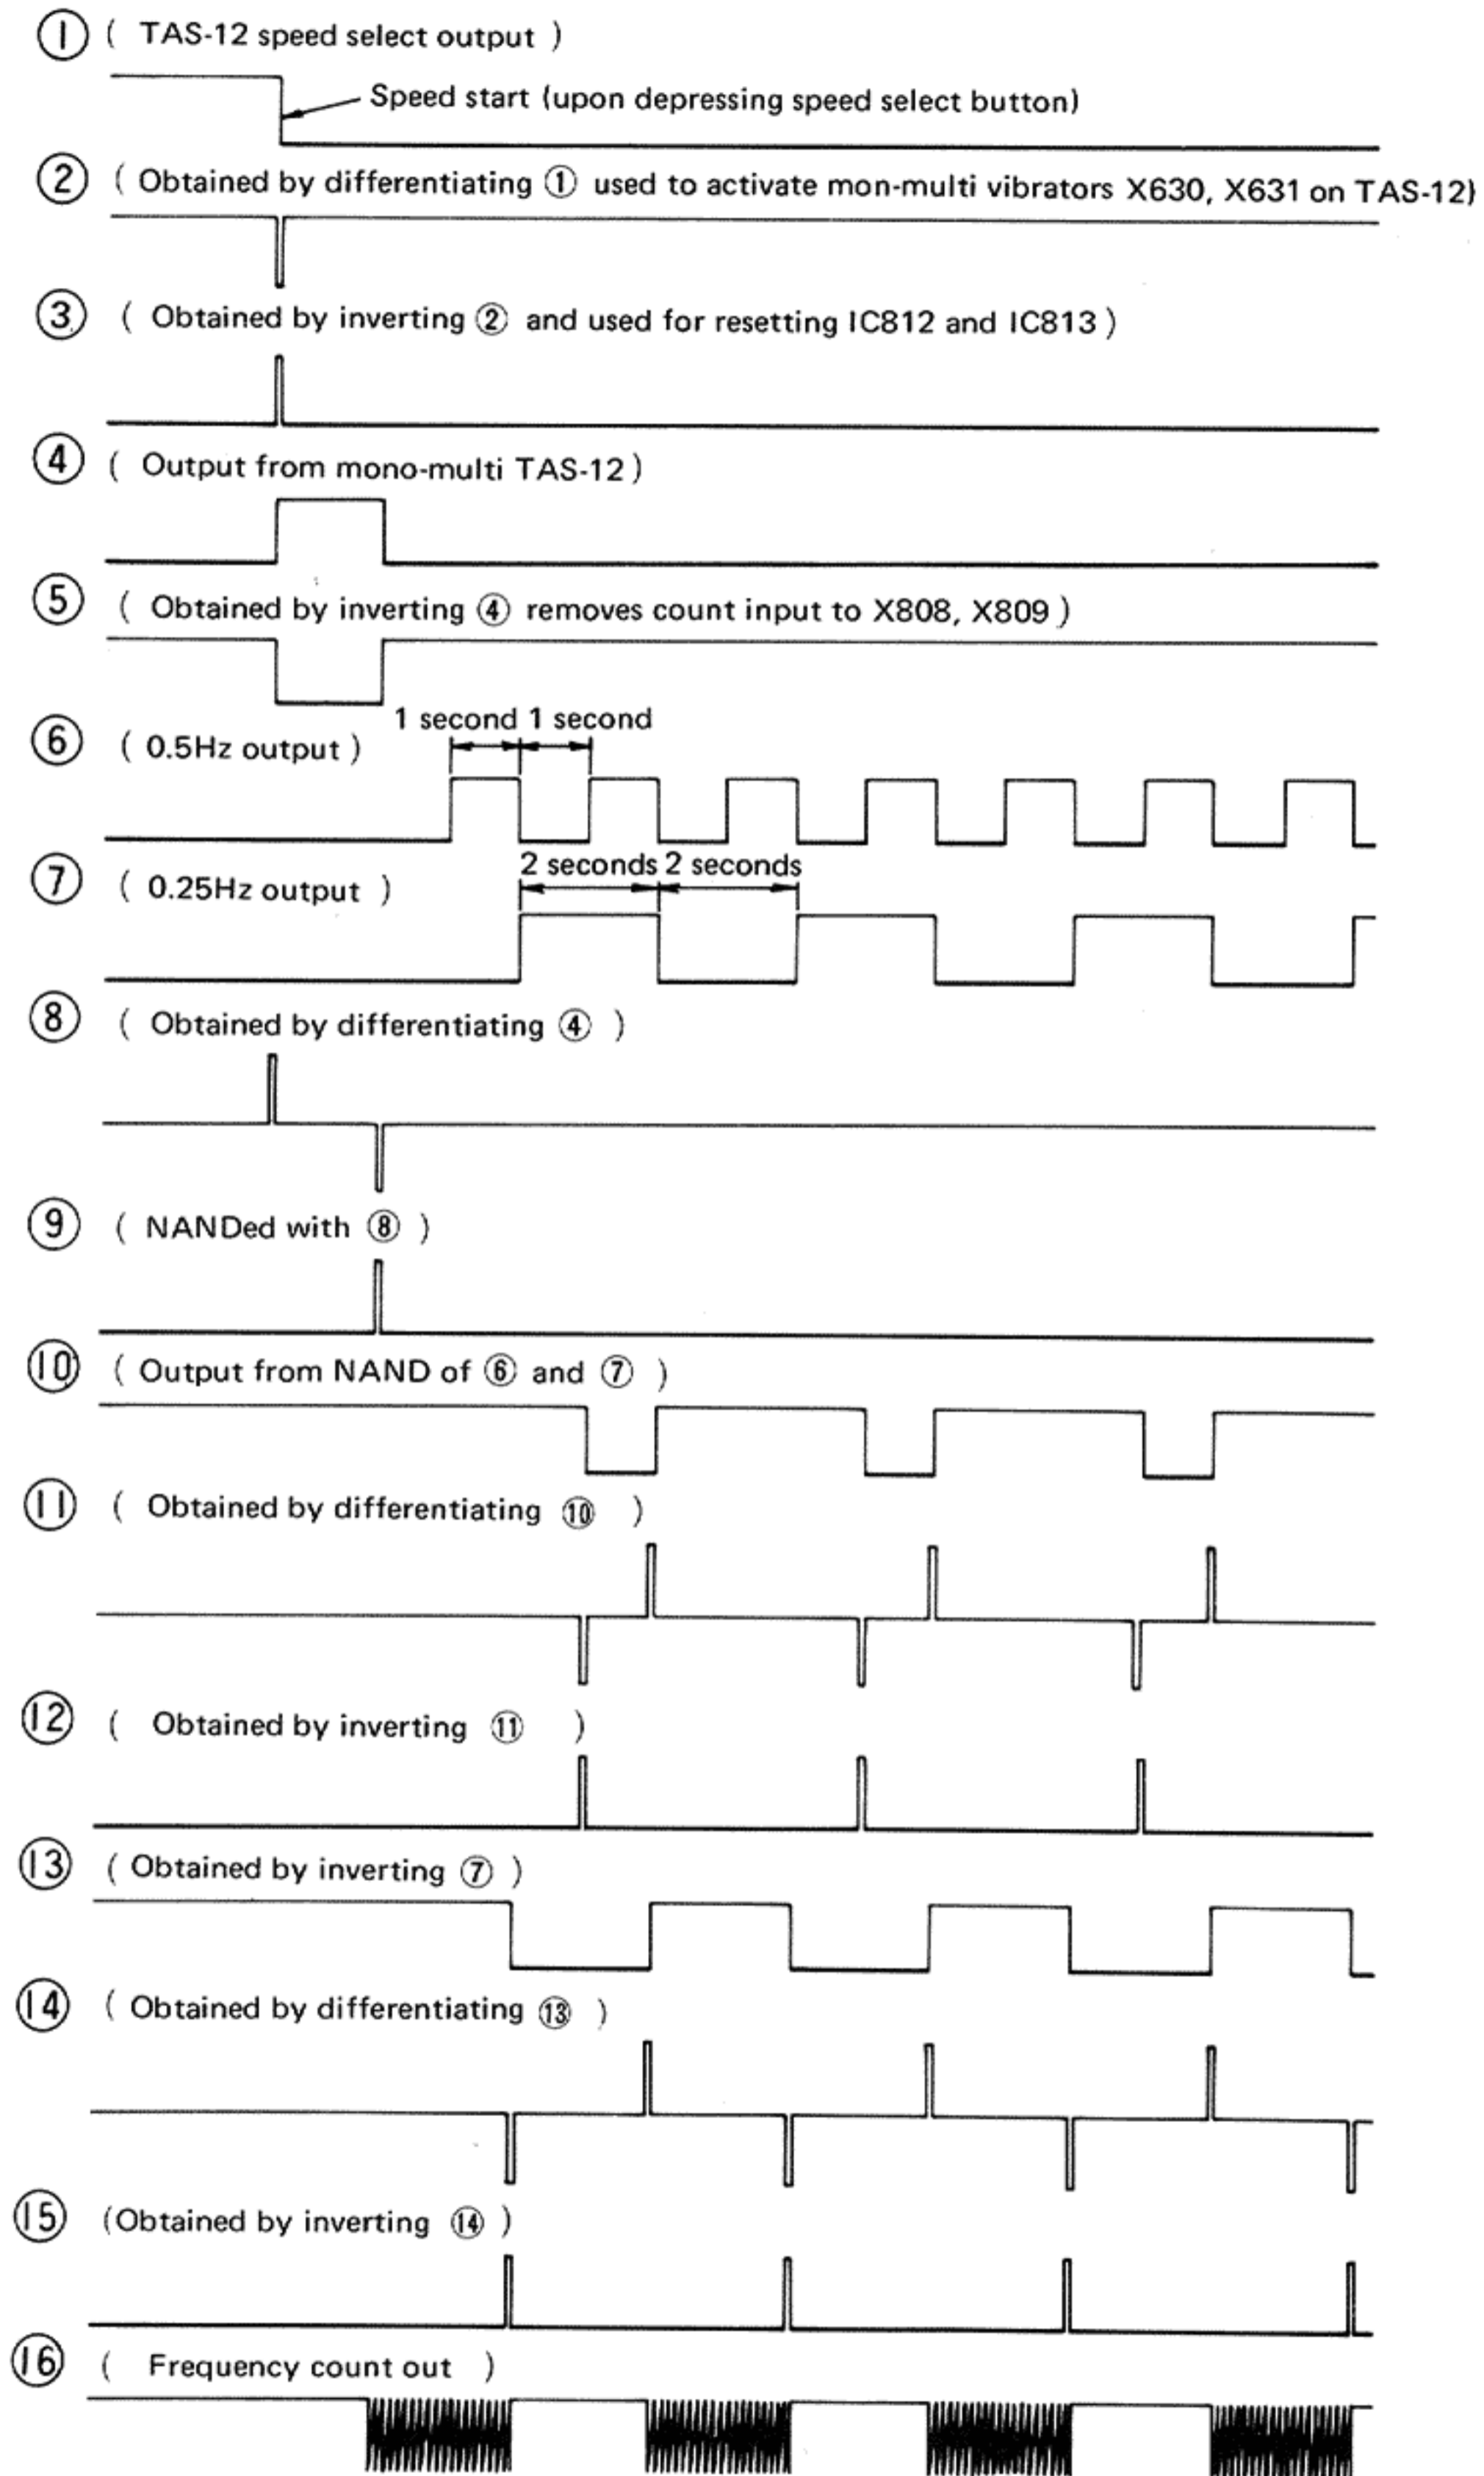

Fig. 15

Count Circuit

1. The count circuit displays the frequency of the input from an external source based on the time base generated by the Time Base generator (See Figure 15).

A. Count set circuit

This circuit creates two square waves of 0.25Hz and 0.5Hz as reset and latch signal respectively.

(1) Reset signal

- The reset signal is used to determine count-start points of the 1/10 Counter and 1/1000 Dynamic Counter and to zero the counters. Counter reset timing is generated by waveforms ⑥, ⑦, ⑩, ⑪ and ⑫ in Figure 15.

- Waveforms ⑥ and ⑦ are input to the NAND gate to produce short-duration minus pulses ⑩ which are differentiated to produce plus and minus spikes ⑪. The spikes are then forced to enter the gate and become plus spikes ⑫. The reset signal is triggered by the last all-plus spike. Figure 16 shows the circuit creating the reset signal.

(2) Latch signal

The latch signal causes the BCD contents of the Dynamic Counter to be output to the indicator circuit. There are two methods of transferring BCD contents. If SW3 is set to the Hold side, the latch signal pulse causes the contents to be transferred in the multiplexing mode, whereas if the switch is set to the Run side, latch pulses are not generated and the contents are transferred in the burst mode. At present, most counters employ the Hold type. The latch signal used with the Hold type is obtained through waveforms ⑬, ⑭ and ⑮ in Figure 15.

Waveform ⑬, which inverts the 0.25Hz time base, is differentiated to become ⑭ of plus and minus spikes. ⑭ passes through an inverter to become the latch signal ⑮ of all plus spikes. A latch signal pulse is generated each time frequency counting is completed as shown by ⑯.

Fig. 16

Block diagram

Fig. 17

B. Dynamic Counter IC813 (TC5001), shown in Figure 15, is a C. Mos LSI which has numerous functions and elements. The device forms a 4-digit indication counter housed in a 24-Pin ceramic package, and consists of ① to ④ 1/10 Decade Counters serially connected to each other. When a frequency is input to the Count Input, each of the four Decade Counters produces a pulse from terminal D every 10th period of the input frequency. This results in the last Decade Counter producing a frequency of $(1/10)^4 = 1/10000$ from the input frequency.

The output from each Decade Counter is input to one of the four "Latches" ⑤ in Figure 17, ANDed with a plus latch pulse input, then output to the Multiplexer as shown in Figure 18 (from A to B).

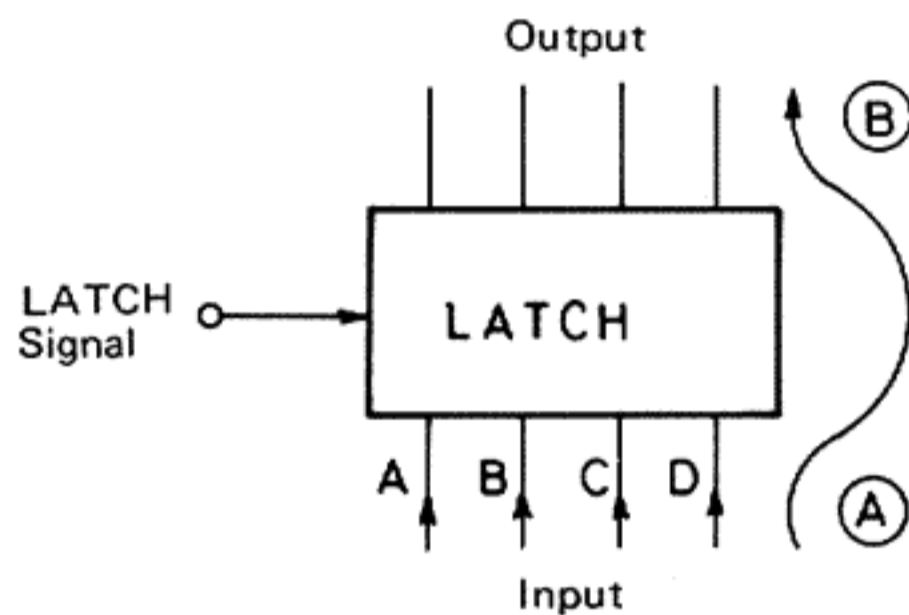

Fig. 18

If the latch signal is High or plus, the Latch Circuit passes the BCD outputs from the Decade Counters without latching them. SCAN OSC ⑥ in Figure 17 is a 2kHz basic oscillator which permits the BCD outputs from the Dynamic Counter to be indicated in sequence. This causes T. Counter ⑦ in Figure 17 to produce T1 through T4 square wave Digit Select Outputs (see TC5001 Timing Chart) to drive Decade Counter respective outputs in the proper sequence.

C. Round-off Counter

A drawback of any digital counter is that the last digit indication is apt to fluctuate. To eliminate this, the 4-digit Dynamic Counter uses 5 Decade Counters, one of which is used to count but not indicate the least significant digit. For example, in the case of 33-1/3 rpm, the indication will be as shown in Figure 19.

The last digit would fluctuate like to 2 or 4.

Fig. 19

Timing chart

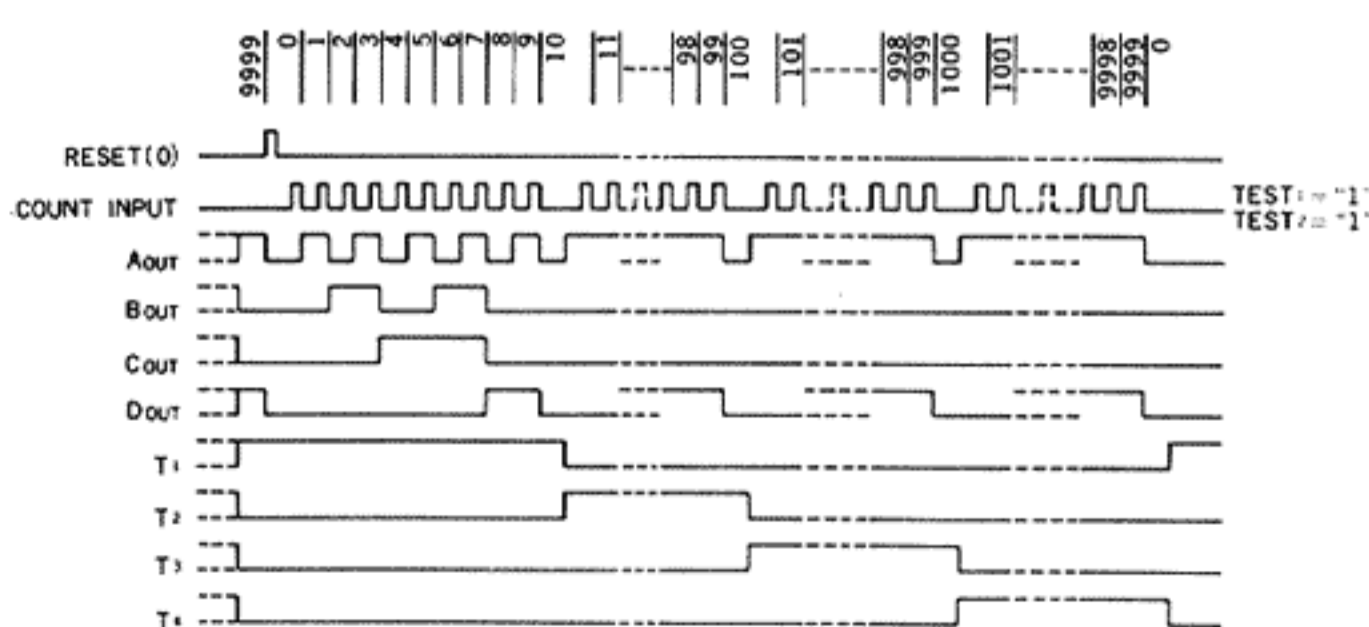

Fig. 20

Indicator lamp drive circuit

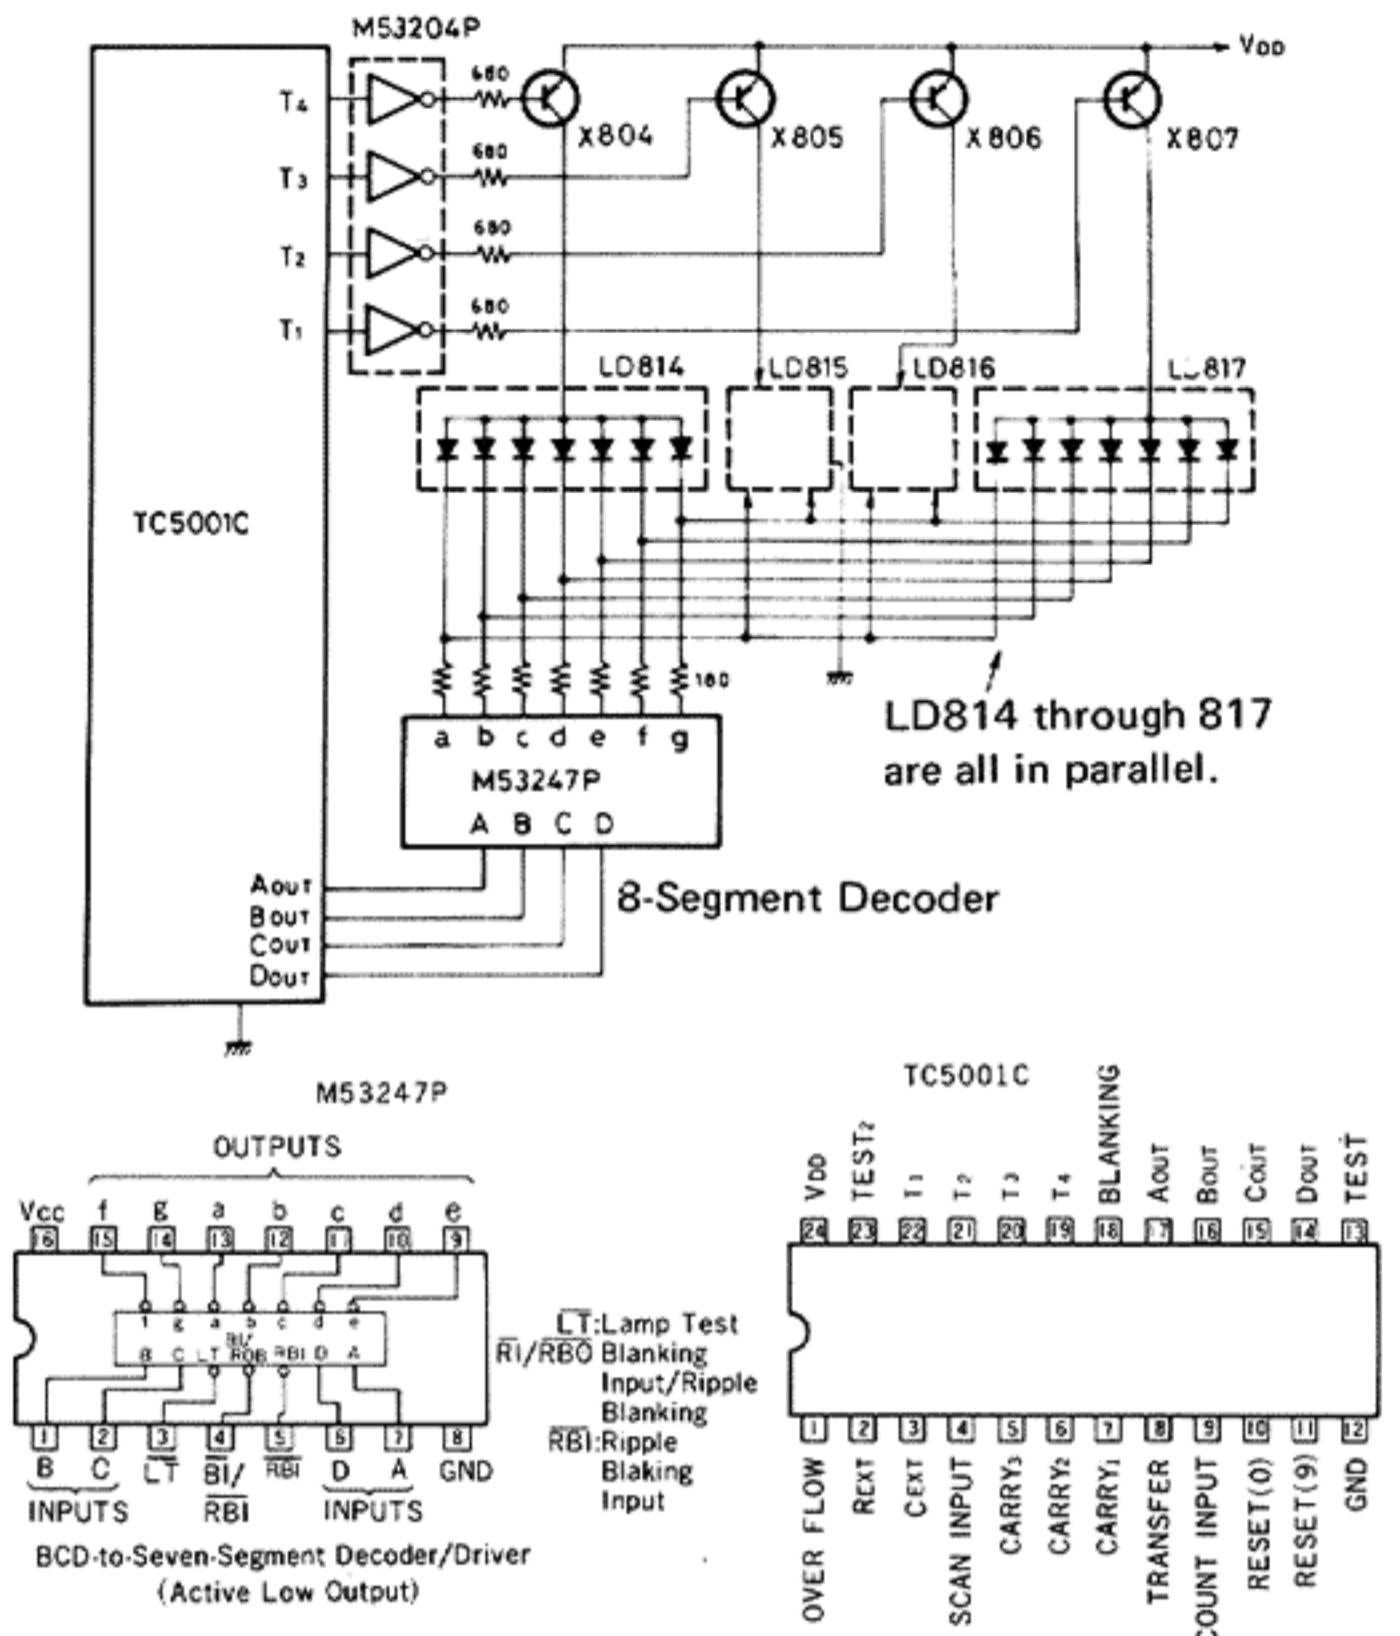

Fig. 21

D. 8-Segment Decoder

IC M53247P decodes BCD outputs from the Dynamic Counter into decimal number digits for indication on 8-segment L.E.D. indicator lamps.

The BCD signals are combinations of High (+5 V) and Low (0 V) levels which can not be used for direct indication. This problem is resolved by the IC logic which decodes the combinations of BCD signals into one of digits 0 through 9.

E. Driver

The L.E.D. display comprises four digits each consisting of 8 diodes. Each of the four 8-segment lamps is sequentially selected and illuminated by turning on the Driver Transistors which are sequentially triggered by timing pulses.

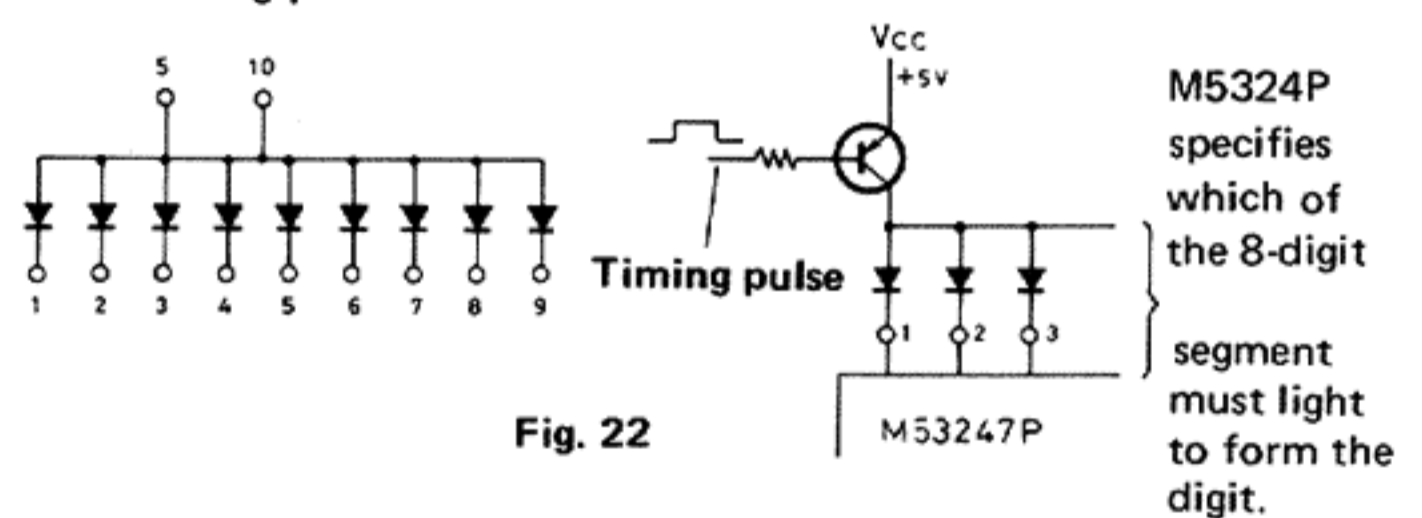

Fig. 22

M5324P specifies which of the 8-digit segment must light to form the digit.

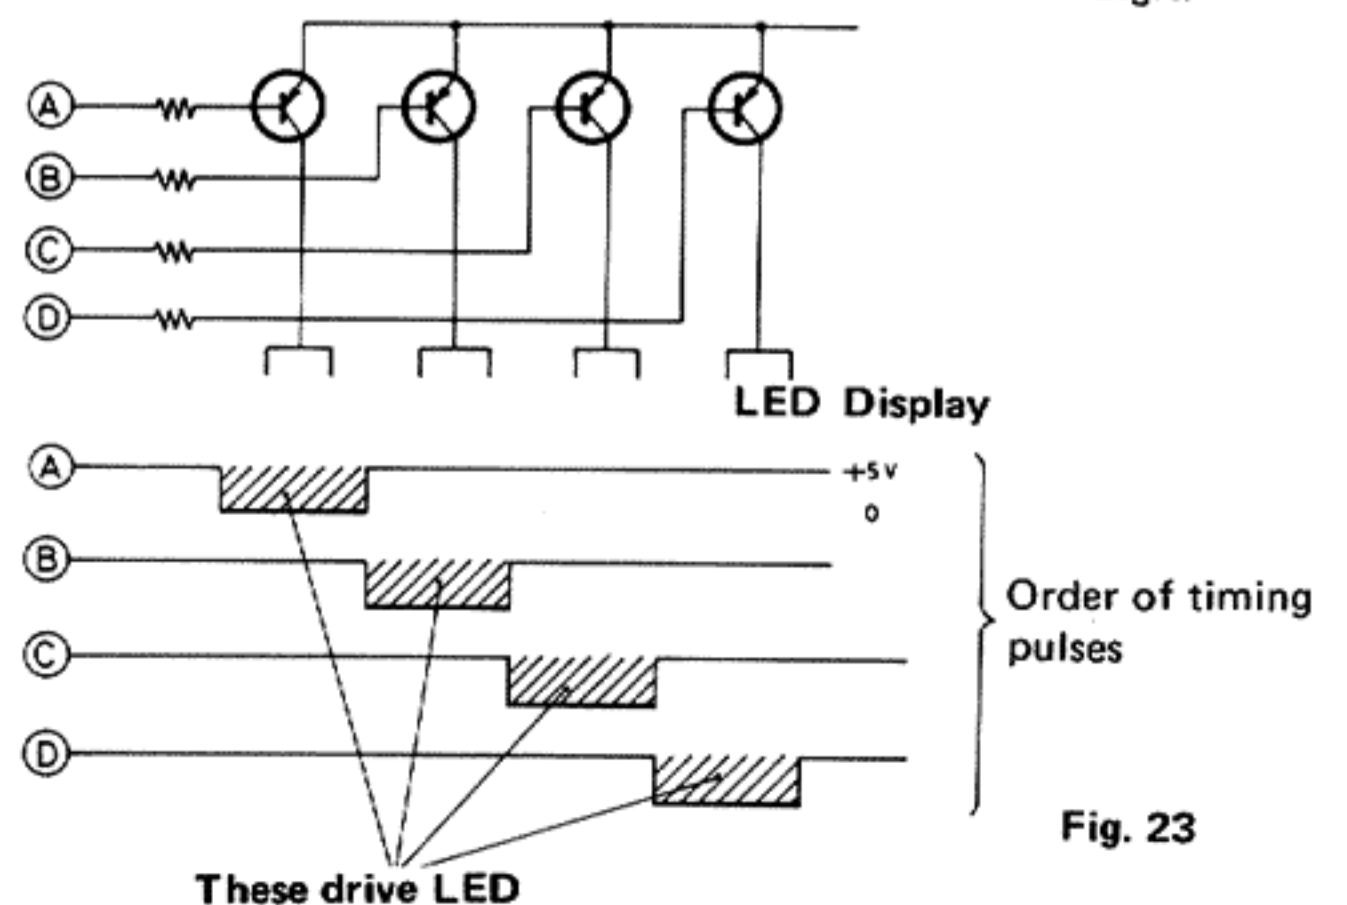

Fig. 23

These drive LED

3-(5) Reverse Turn Detection

2. Prevention of error indication and miscount

Care has been given the Count Circuit to eliminate errors which may occur during the interval from application of power and depressing the speed select button to indicating the frequency, as follows.

A. At speed start

The output ① in Figure 15, produced by a flip-flop in the Speed Select section, is differentiated to produce a spike in High-to-Low transition, and used to drive the monostable multivibrator, consisting of X630 and X631, which makes the collector of X633 High for about 1.4 seconds (as shown by ④), thus causing the Count Set circuit to stop counting the time base frequency. At the same time, the minus spike is inverted and used to reset IC812 (M53290P) and IC813 (TC5001C), thus making the contents of both ICs, zeros or empty.

Further, to prevent frequencies from being input to the counters during the 1.4 second interval from the start, signal ⑤ obtained by inverting ④ is input to Pin 10 of IC801 thereby attaining completely fail-safe operation.

B. "Zero" indication at start time

At speed start, the counters do not have inputs thus contain zero contents. Then 1.4 seconds after start, the status is indicated by the LED indication lamps utilizing the latch signal ⑨ in Figure 15.

C. 2-second count time

The frequency generated by revolution of the turntable through the F-G coil is 100Hz at 33-1/3 rpm or 135Hz at 45 rpm, which is too slow for the counters to actually perform counting. Therefore, the frequency is multiplied by 1000 to yield a count time of 2 seconds. The time required for one revolution of the turntable is 1.8 seconds at 33-1/3 rpm. Though the time of each revolution deviates due to various reasons, indication is stabilized by continuous counting, i.e. for more than 1.8 seconds and averaging the results. It is desirable for counters to accurately count as quickly as possible. However, counting too fast will result in reflecting the revolution deviations on the indication, thus causing indicator fluctuate which tends to confuse and/or make the observer uneasy. This is the reason the count time frequency is not multiplied by the N-time counter.

(1) Necessity for reverse turn detection

The reverse turn detection circuit serves to restore forward turns, as soon as possible, after an external reverse turn force is applied to the turntable. In the past, this purpose was served by conventional servo motors which were employed to react after revolution had reached the rated speed of 33-1/3 or 45 rpm. This method, however, was inconvenient.

(2) Detection

Detection is performed by the reverse turn detection magnet attached to the rotor by a bracket, and the fixed hole element.

The detection signal waveform is generated utilizing magnet polarities and pulse generation phases of the hole element. In the case of normal (clockwise) movement, the N polarity of the magnet first passes the hole element and produces the waveform shown in the upper part of Figure 24.

Fig. 24

This waveform on X603 of the positive feed-back flip-flop consisting of X603 and X604, while the collector of X603 is grounded. The state remains unchanged despite the succeeding arrival of like type waveforms. If a reverse turn force is applied to a turntable which is turning forward, such as pressing with the finger, the S polarity of the magnet first passes the hole element and produces a waveform such as that shown in the lower part of Figure 24. This causes a negative pulse to be applied to the base of X601 to reverse the state of the flip-flop.

When revolving normally, the base of X608 is Low and X608 is cut off. Whereas in reverse, X608 is turned and the collector is grounded. Grounding the collector activates the emitter of X663 in the Phase Comparison section to produce the drive force necessary to restore the forward movement.

Reverse Turn Detection

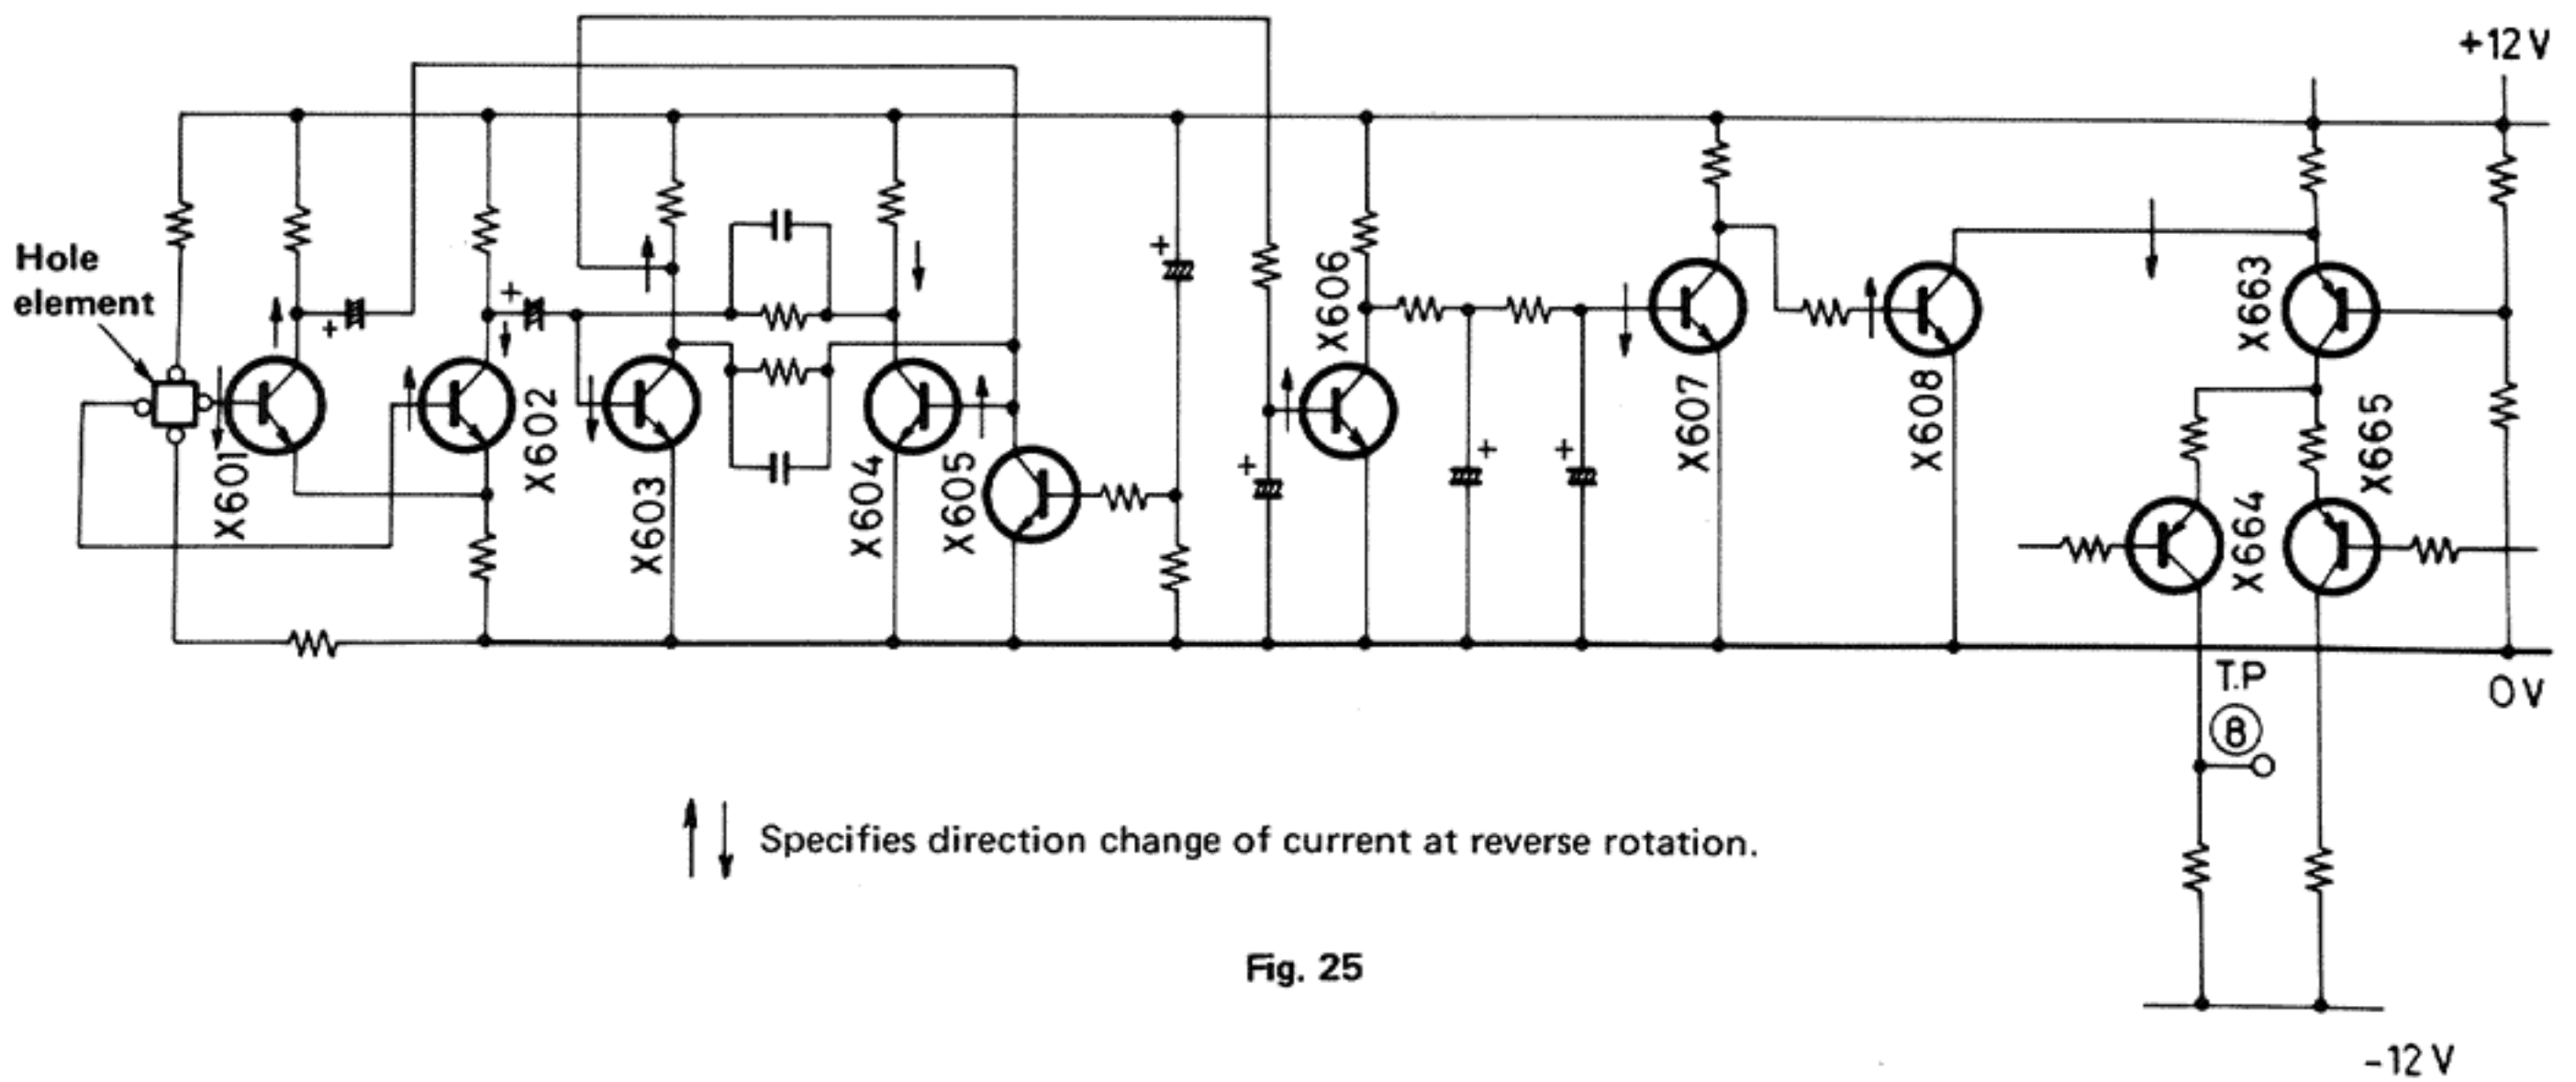

Fig. 25

Reverse turn detector magnet mounting drawing

Fig. 26

3-(6) N-time Counter

The N-time counter utilizing P.L.L. multiplies the frequency of the input from the F-G coil without changing its phase.

1. Block diagram

Figure 27 shows block diagram of the N-time counter.

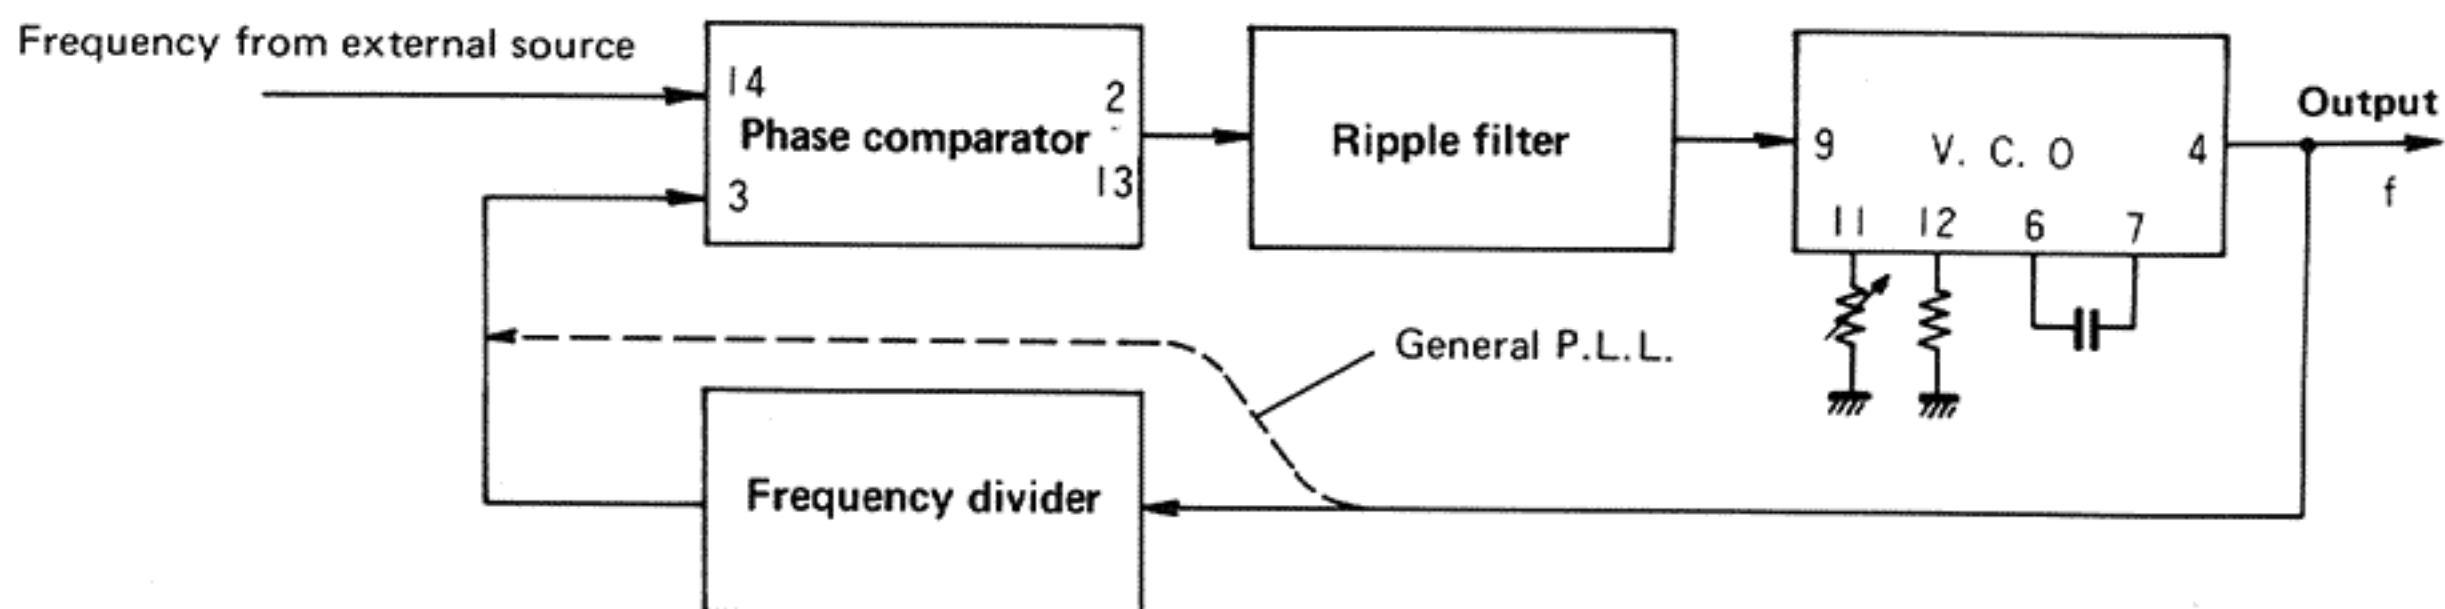

Fig. 27

2. Operation

The phase comparator compares the phase of external frequency A with that of feed-back frequency A'. If a phase deviation is detected, a phase comparison output such as that shown in Figure 28 is produced. This output consists of sharp square pulses, which must be flattened by the ripple filter before being input to the VCO. The VCO (Voltage Control Oscillator) is capable of varying the oscillation frequency, according to the input voltage, over the range from Fmin to Fmax which is 2 times Fmin. f_0 is determined by R684, VR685 and C630, and is selectable within this range. The oscillating frequency from VCO is converted into an impedance value by buffer X653 for input to the frequency divider. The same is also sent to the gate of the frequency counter. Frequency divider IC606 (M53292P) divides 100kHz (at 33-1/3) into 1/6 to obtain an output of 16.666kHz. The frequency counter, on the other hand, divides 100kHz into 1/1000 utilizing three decade counters. The output from IC603 is made identical to the input frequency 100Hz.

Fig. 28

Fig. 29

3. Frequency lock circuit

The frequency lock circuit locks the output at a frequency within the Fmin through Fmax range of approximately $2 \times F_{min}$. Since stability exists outside of the range, locking at these ranges is easily attained. For 100Hz at 33-1/3 rpm, F_{min} is set to 80Hz, and for 135Hz at 45 rpm, F_{max} is set to 155Hz, thus providing ample coverage.

Fig. 30

N-time counter

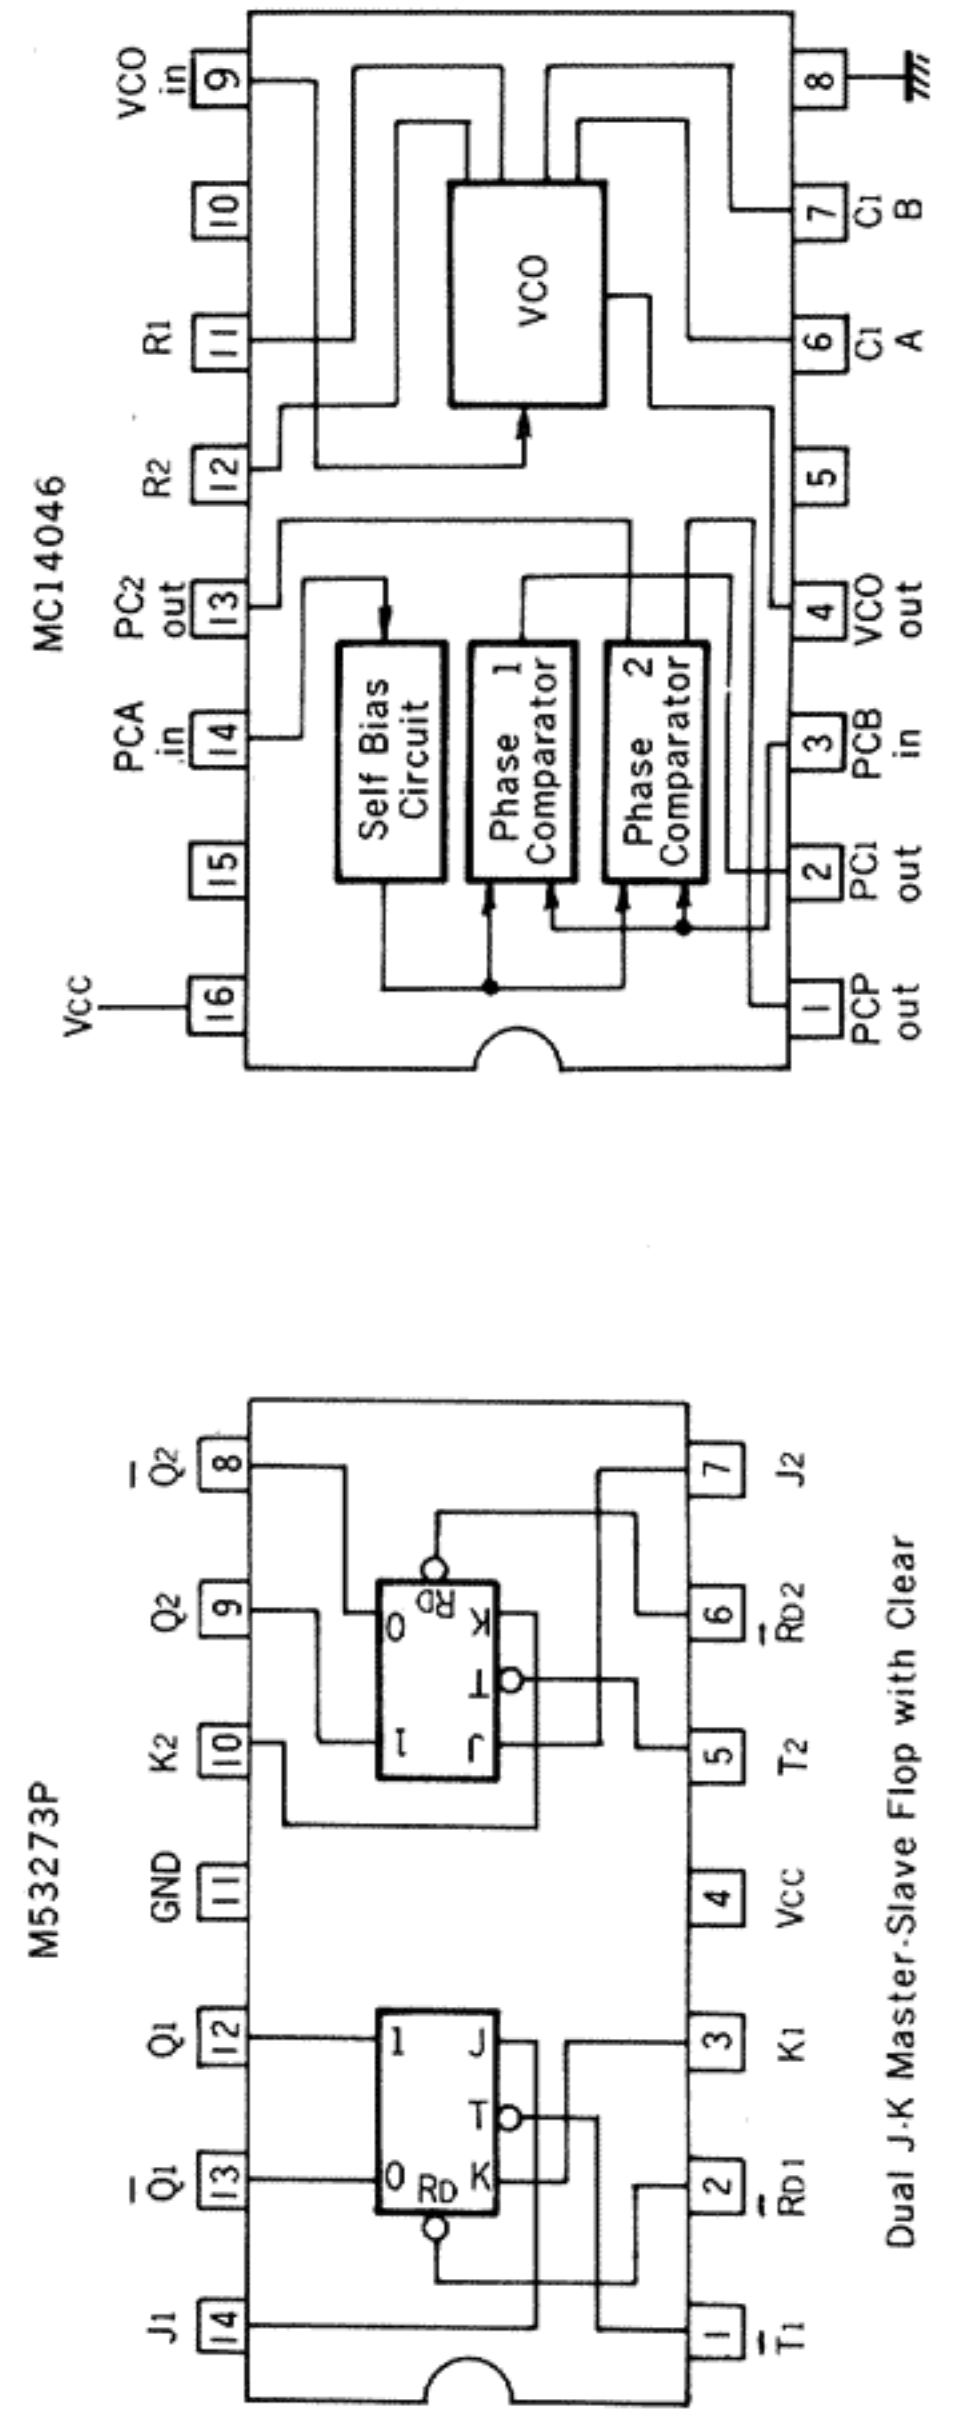

Fig. 31

Equivalent circuit of M53292P (for reference)

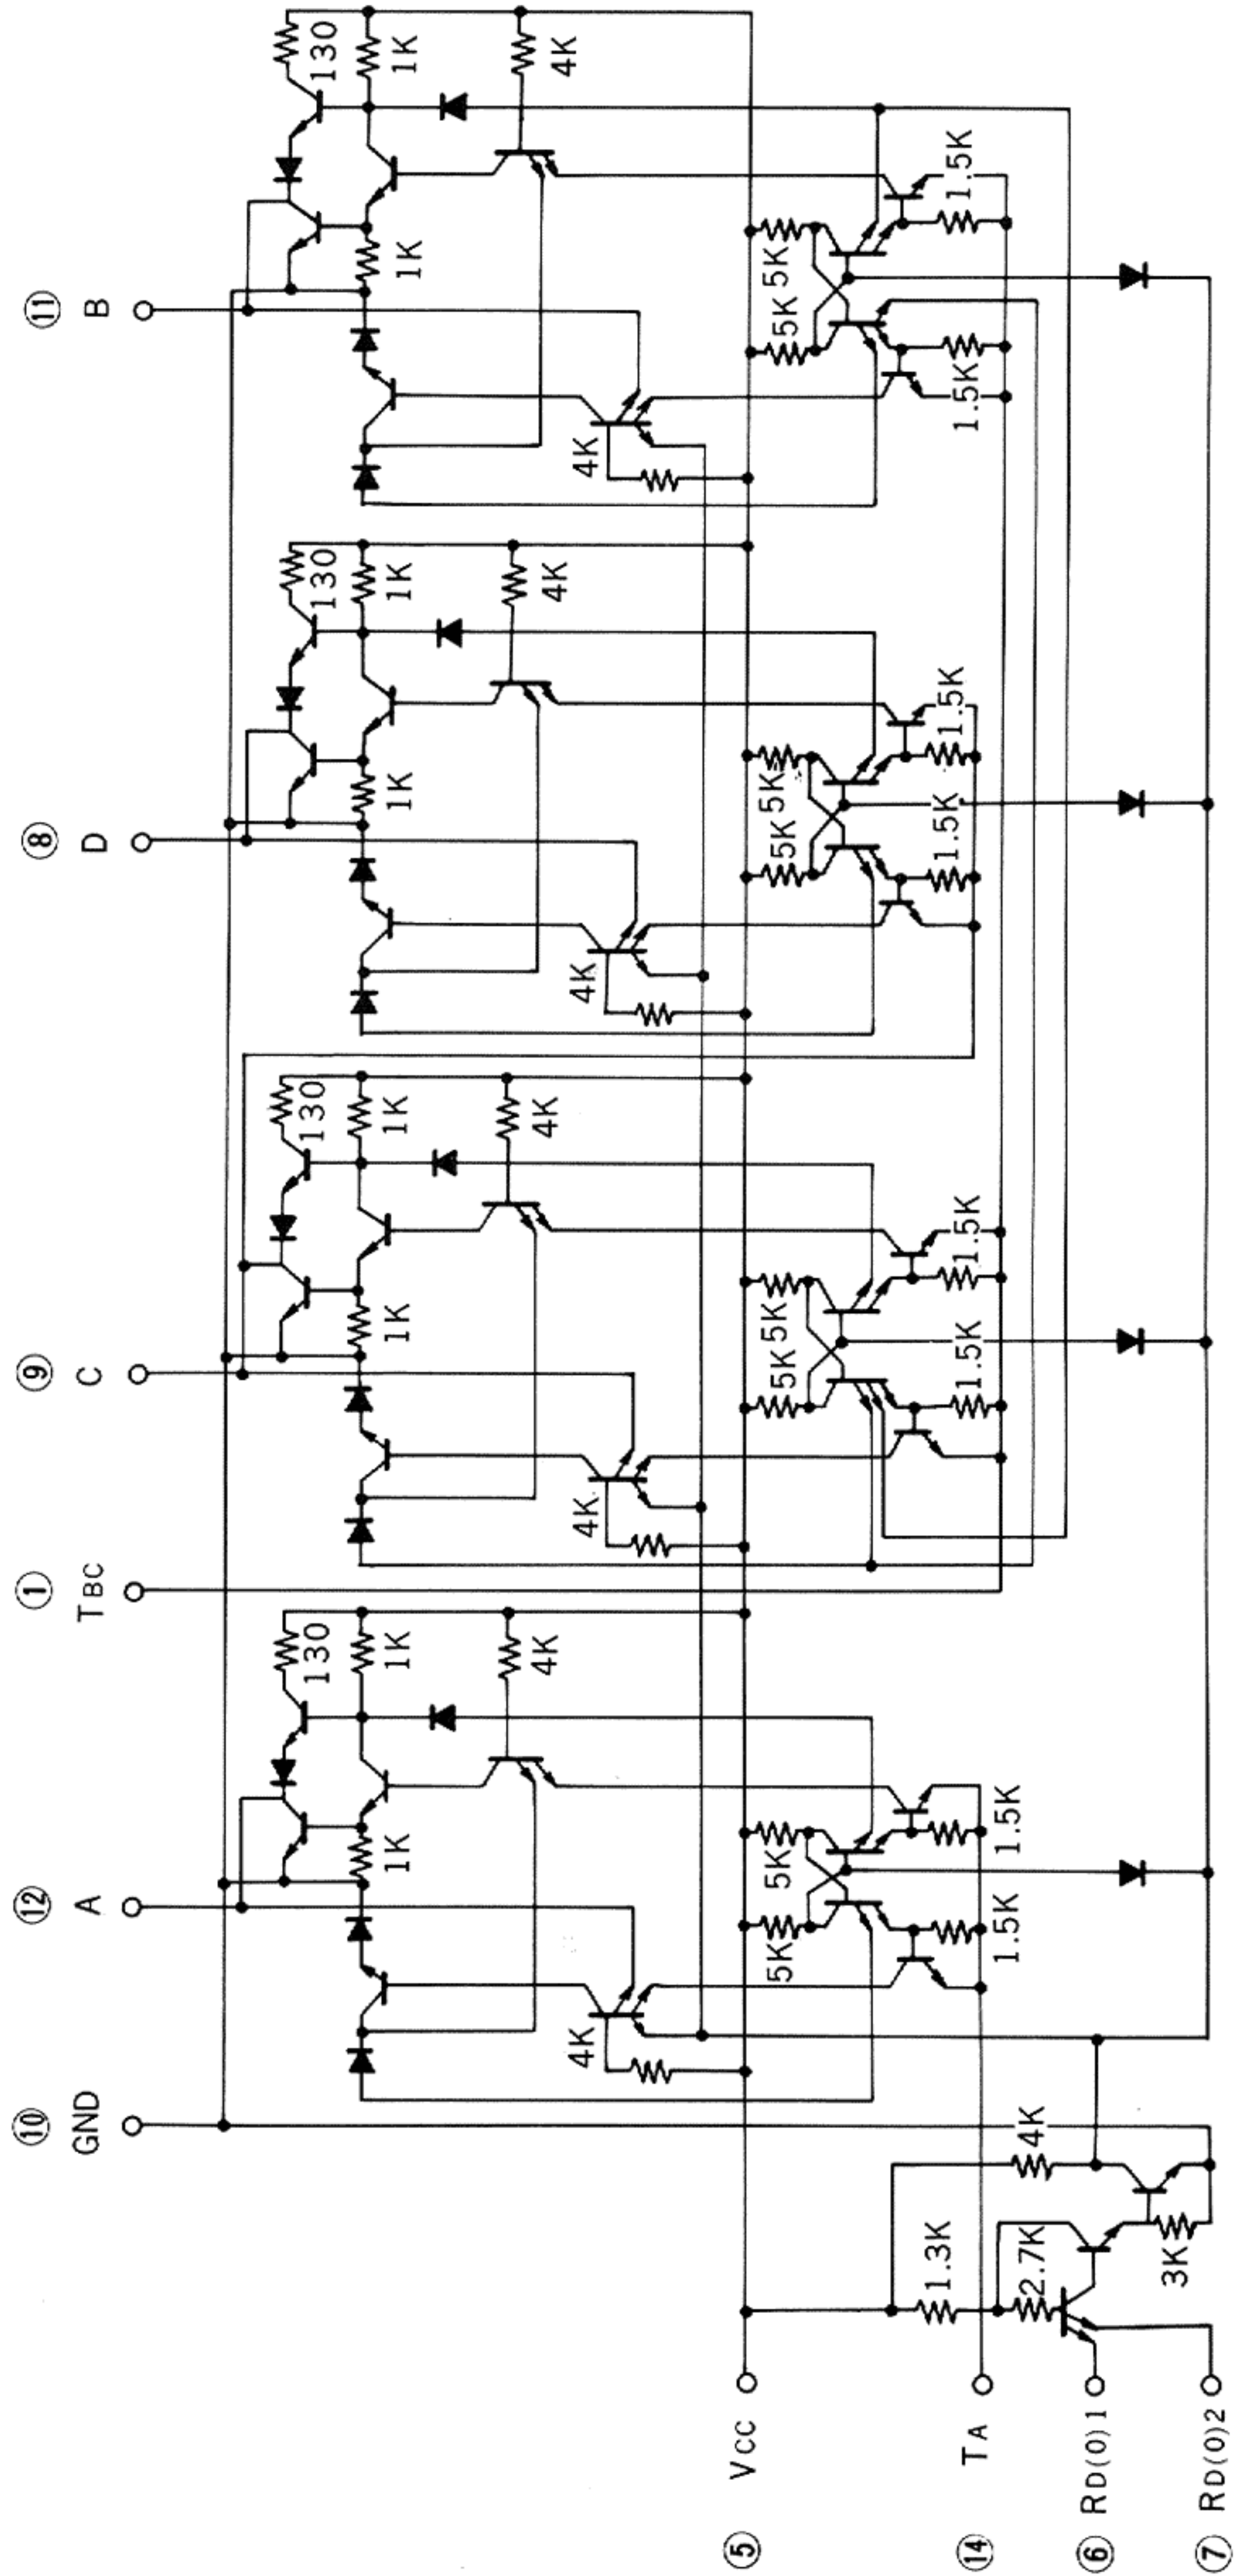

Fig. 32

3-(7) Timer

The timer enables the motor to stop automatically within 16 seconds after the turntable is forcibly locked, like with the hand, to prevent the motor from overheating.

1. Current detection

As shown in Figure 34, a 10-ohm resistor is inserted in the emitter common to power transistors X684 and X686 which are serially connected to the motor-drive coil. During the start interval or when the turntable is forcibly locked, approximately 3V is applied to the resistor whereas when turning at a normal speed, the transistor current is quickly reduced, thus lowering the voltage to between 0.2 and 0.3V. The current through the power transistors is detected by utilizing the difference between the above voltages. This timer starts functioning when the voltage exceeds 1.5V.

2. Set/reset

When employing a record cleaner which causes intermittent locking of the turntable or when the turntable is stopped for less than 16 seconds, the turntable may be made to automatically restart by resetting Pins 2 and 3 of IC607 to High level.

Fig. 33

3. Timer operation

When a 0.5Hz input is applied from TDC-7 to D631, the resulting output from IC607 becomes 1/8 of the frequency thus permitting Pin 8 to turn from Low to High upon arrival of the 8th pulse, which is sent to the base of X610 to activate the stop circuit and turn off the speed select circuit.

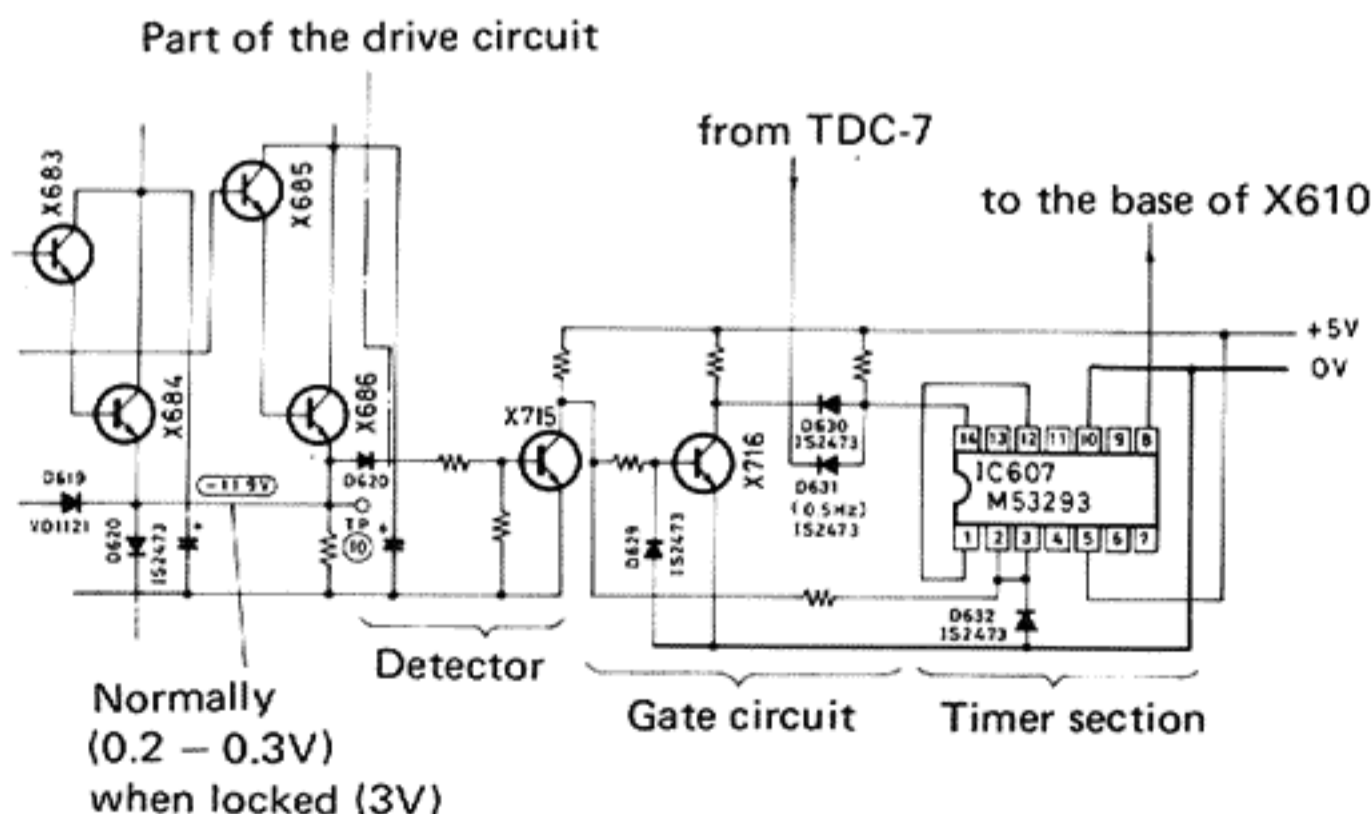

Fig. 34

3-(8) FM Demodulator and Phase Comparator

1. FM demodulator

A 100Hz (33-1/3 rpm) or 135Hz (45 rpm) output of approximately 0.5mV from the speed detector is amplified by X641 through X652 into a 24V square wave as shown by (A) in Figure 36. The square wave is differentiated to obtain pulses as shown by (B). If each (B) positive pulse is input to the base of X658 the collector of which is connected to the power supply charged C640 (0.1μF), X658 starts to conduct and the collector voltage becomes 0V. After the disappearance of the pulse, the capacitor is again charged through R736 and VR735. This process is repeated to generate a sawtooth waveform as shown by (D) in Figure 36 from the collector of X658. Conversely, X655 is supplied negative to produce pulses with polarities opposite to (B) pulses. The pulse output causes X659 to conduct, and a sample-hold-ripple DC (E) in Figure 36) to be obtained from the FET X660 source.

2. Phase comparator

A 100Hz (33-1/3 rpm) output from IC SC3042 is applied in the waveform shown by (G) in Figure 36 to X669 of this new phase comparator. The output from X669 is differentiated for input through X668 to X667 as a sample hold input. The sawtooth waveform (D) is applied to the source of X667. Since the input (G) from the quartz crystal has a constant frequency. A decrease in the sawtooth waveform will result in ladder step voltage rises as shown by (J). A stabilized DC (E) is ultimately obtained from the differential amplifier consisting of X664 and X665. This produces a voltage between the ends of R750 (22kΩ) to ensure a constant revolution speed.

FM demodulator and phase comparator

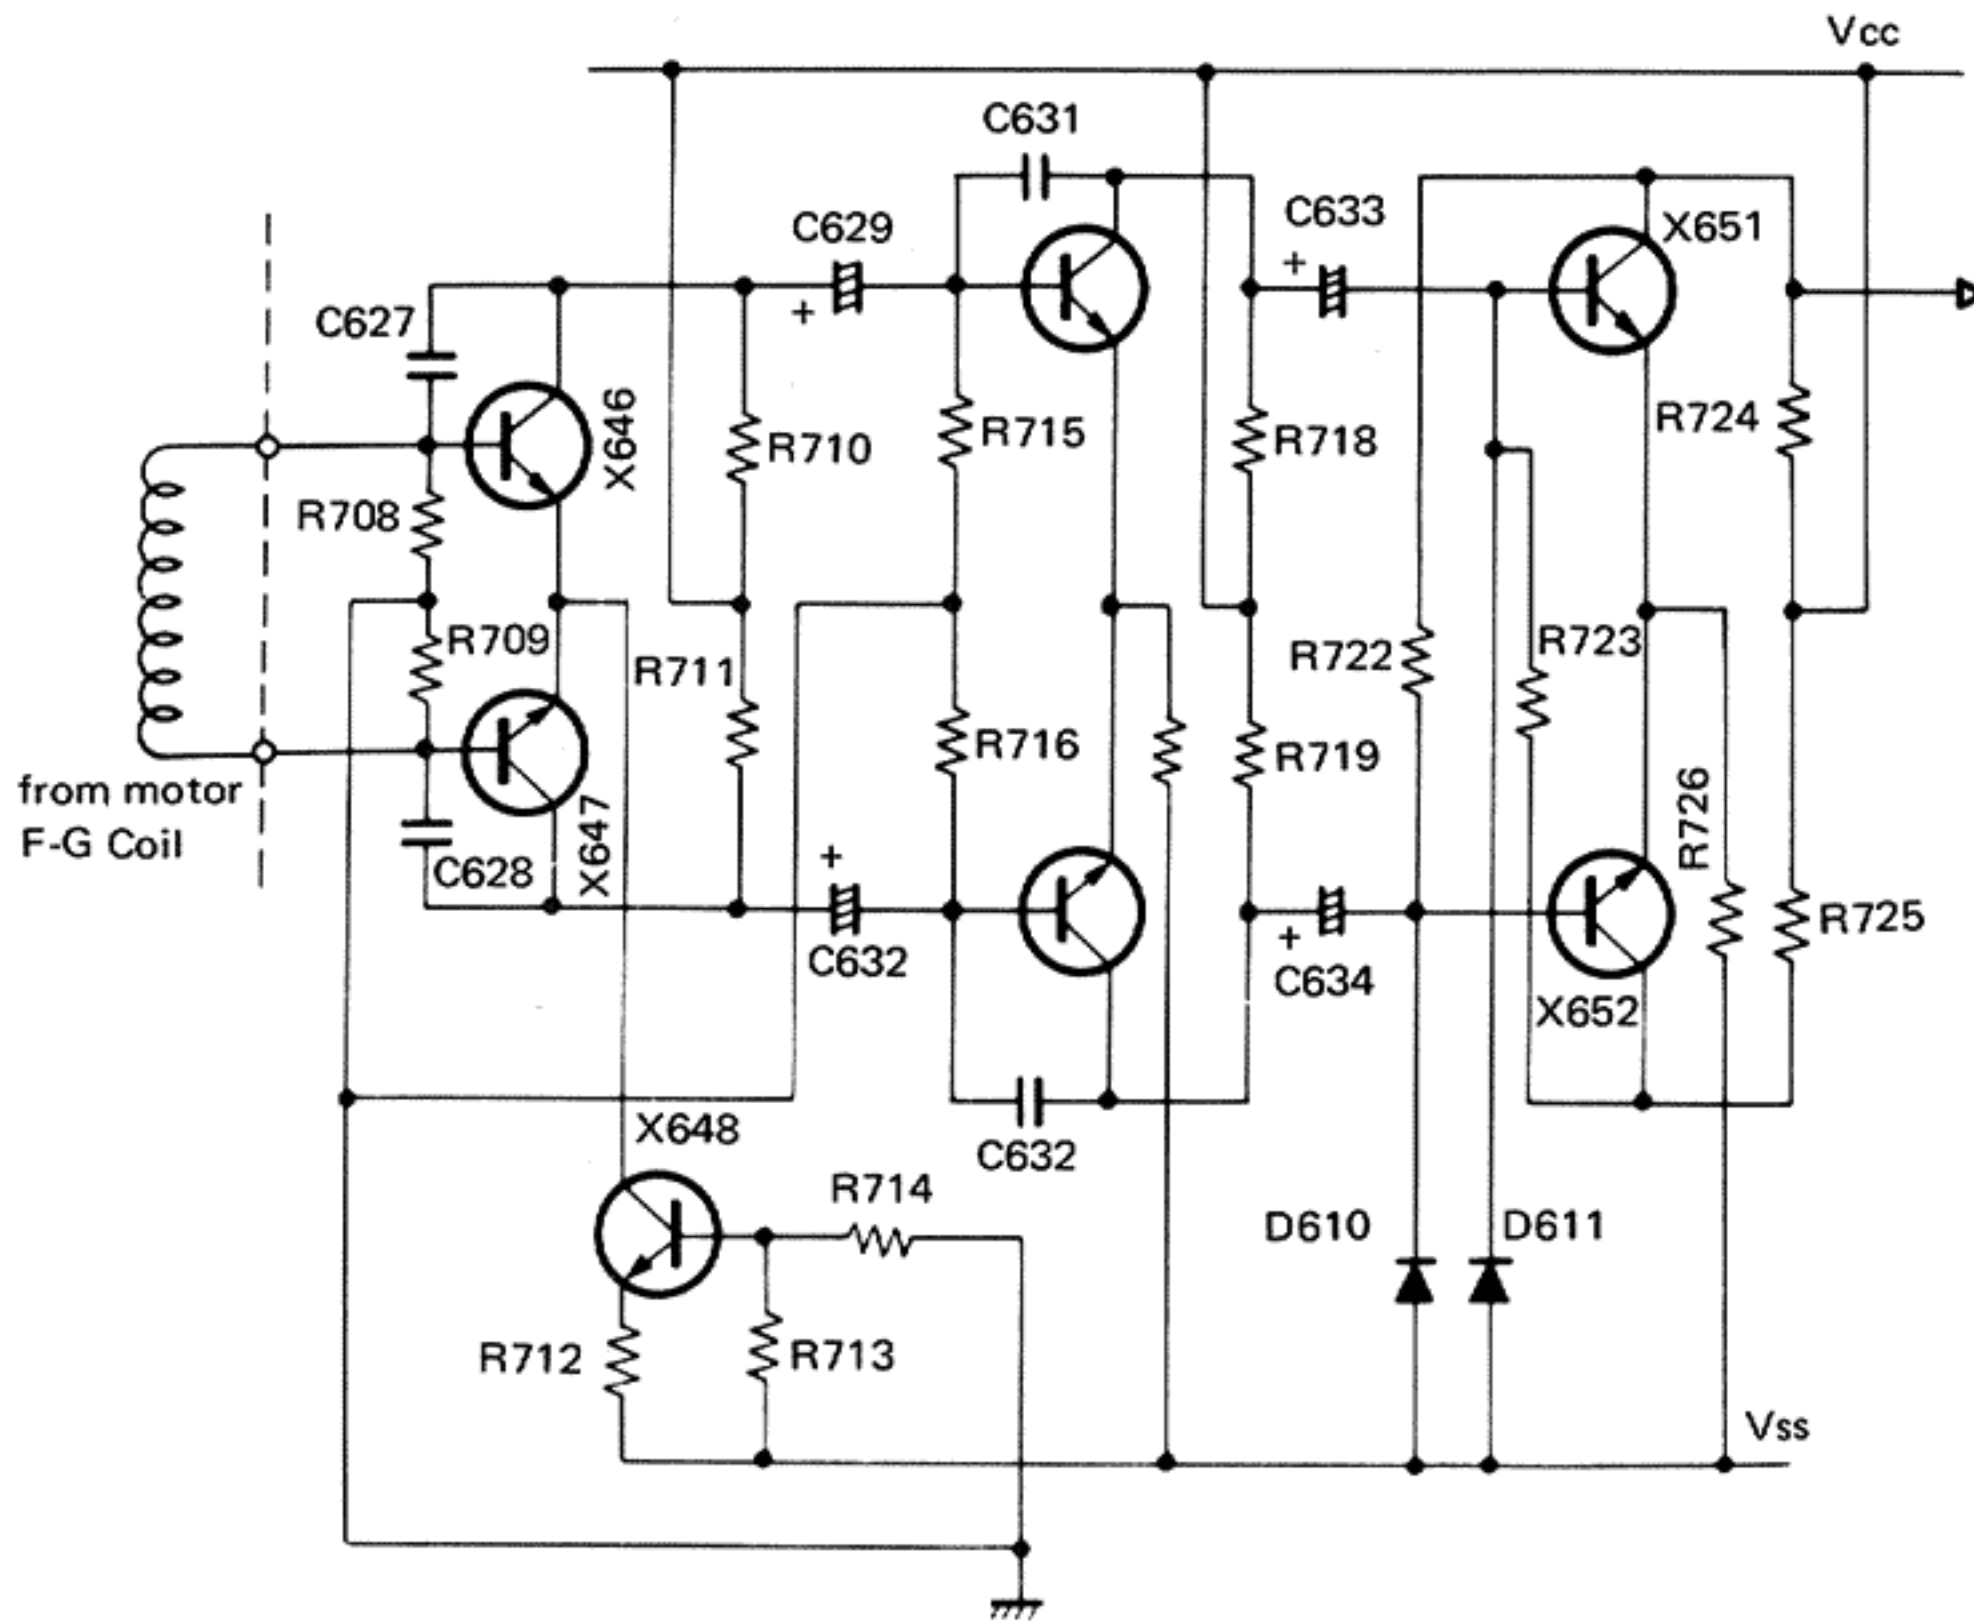

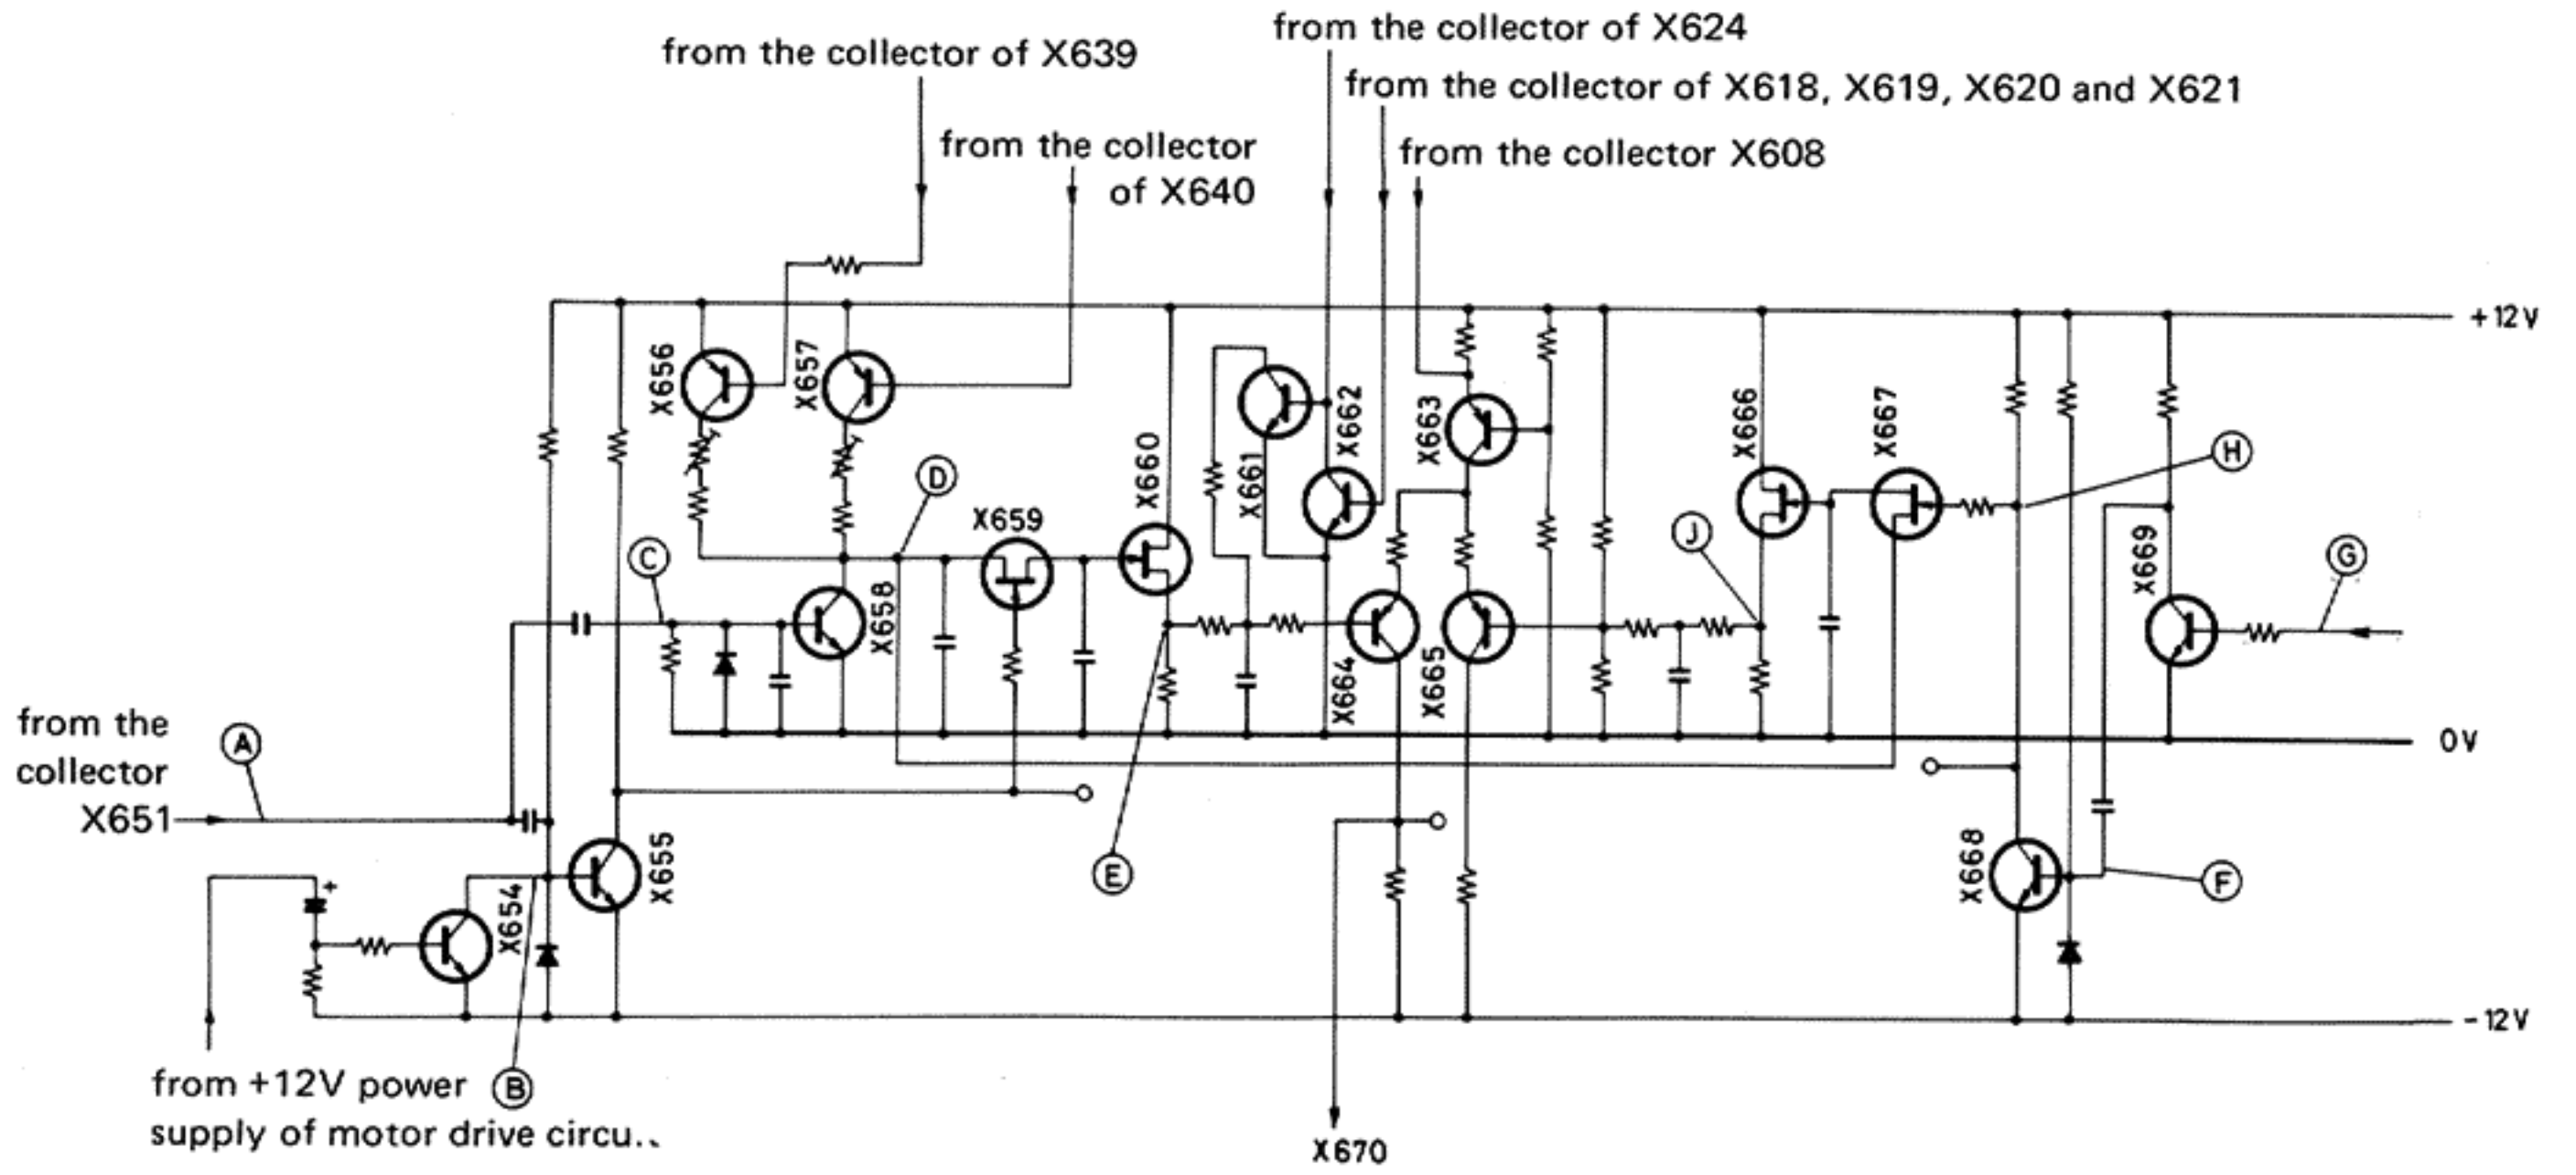

Fig. 35

3-(9) Drive Start Circuit

FM demodulator section in encoder

Output voltage of (E)

If pulses of (A) are demodulated, voltages/frequencies shown in the left are obtained.

Fig. 36

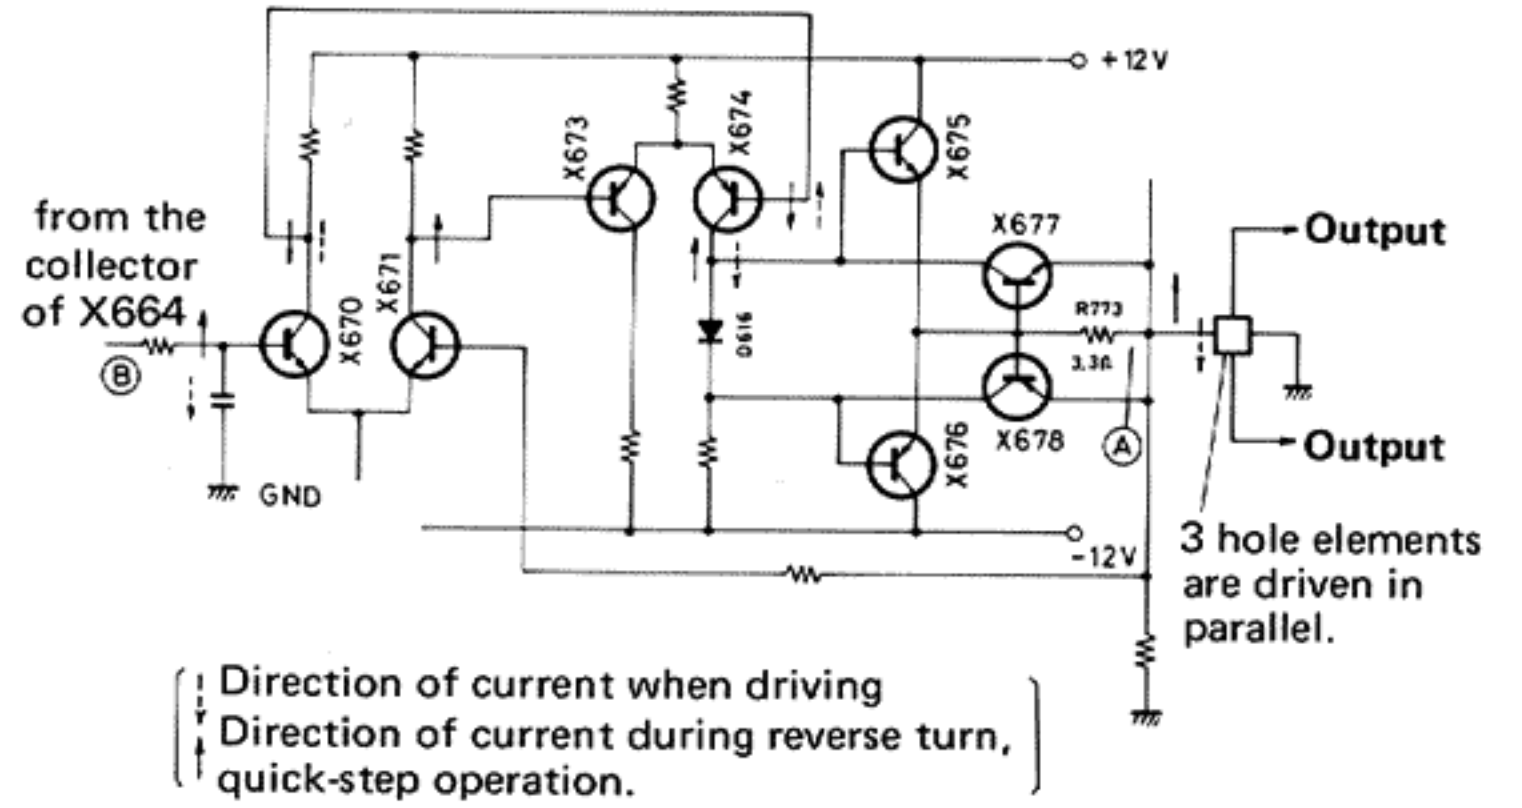

Fig. 37

This circuit DC-amplifies the output from the phase comparator and provides current to the hole element.

The voltage polarity changes at both (A) and (B) points are identical, therefore an identical, amplified version of the output from X664 is obtained from output point (B). X667 and X678 protect the hole element from damage due to an excess current. If an excess current flows in X667 and X678, the collectors and emitters of both transistors are short-circuited, and the output is terminated at the last stage.

3-(10) Motor Power Switch

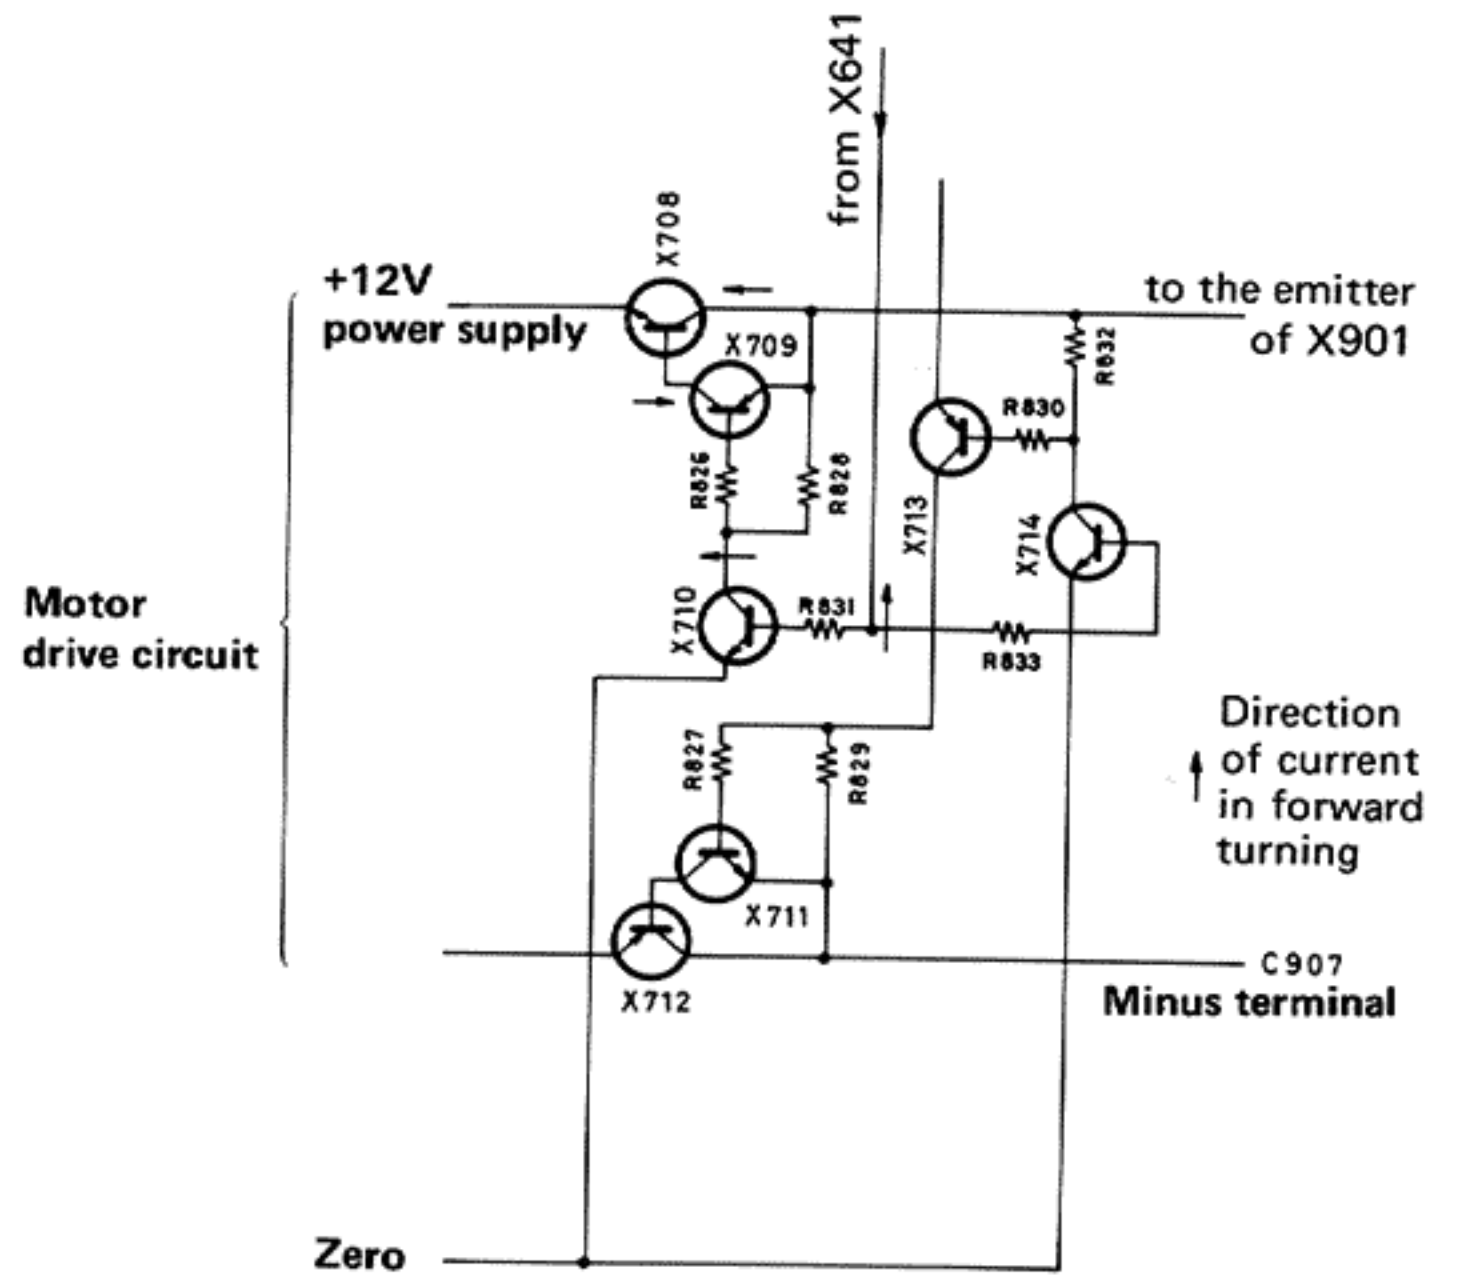

Fig. 38

The electronic motor power switch in the motor drive circuit causes the collector of X641 High to turn on X708 and X712, if the turntable is rotating at 33-1/3 or 45 rpm, thus transferring the power supply circuit voltage to the motor. The turntable is stopped by changing the collector of X641 Low, thus cutting off the current supply to the motor drive circuit.

4. Disassembly

3-(11) Speed Selection Circuit

Fig. 39

The basic speed selection circuit is as shown in Figure 39. If one of the transistors X609, X613 and X615 is in the OFF state, the other two are in the ON state. For example, if the collector of X609 is +V, currents flow to the base of X613 and X615, thus causing them to conduct and their collectors to obtain the same level as VCES.

However, unless the circuit is modified slightly, it is impossible to foresee which of the three transistors will go OFF first immediately after applying power, since this is dependent upon dispersion of transistor characteristics and the PCB pattern layout.

Therefore, an additional transistor is inserted into the base of, for instance X609, to make it the first to go OFF immediately after turning the power switch on. As shown in Figure 40, immediately after the switch is turned on a current flows through C610 to the base of X611 to turn it on. This cuts off the current to the base of X609 and turns it off.

Fig. 40

The above action results in a high X609 collector voltage which causes current to flow to the base of X613 and X615 to turn them on. This state produces zero rpm of a speed select off condition.

Fig. 41

- (1) Remove the three screws ① and the control panel lifts off.
- (2) Remove the three screws ② and two screws ③, then remove the cover.

5. Adjustment Procedures

Special precautions

- Power on/off
Do not turn the power on until all required connections between circuits have been completed. Do not insert or remove plugs while the power is on.
- Handling of C. MOS
C. MOS IC801, IC813 and IC602 are very sensitive. Therefore, care should be exercised to prevent contact with other components in replacement, or current leaks may result. Maintain the same voltage level for all elements.

5-(1) Adjustment of TPS-41B Power Supply P.C.Board

- +12V adjustment**
Supply the rated voltage of AC 100V 50/60Hz to the primary, then adjust VR905 until the voltage between the 1st and 3rd terminals of S⑥ on TPS-41 is +12 ±0.2V. (note: the 1st terminal is the positive side)
- 12V adjustment**
Adjust VR909 until the voltage between the 3rd and 6th terminals of S ⑥ is +12 ±0.2V. (note: the 3rd terminal is the positive side)
- +5V adjustment**
Adjust VR912 until the voltage between the 5th and 3rd terminals of S ⑥ is +5 ±0.2V. Insert a 10k-ohm load resistor between the terminals. (note: the 5th terminal is the positive side)

5-(2) Motor Adjustment (TAS-12B)

- 2.2Hz adjustment**
 - Remove the quartz lock. (Extract J1 jack from the TDC-7 digital PCB.)
Insert a 680-ohm resistor and a 220µF ±20% capacitor into TP ⑧ after starting the motor. (see Figure 42)

Fig. 42

- Start the adjustment approximately 2 minutes after power on and motor start. Connect the probe of an oscilloscope (storage type) to TP ⑩ and set the vertical scale to the 20mV/div of 50mV/div scale in the DC coupling mode. Adjust VR779 to obtain optimum waveform display.

Fig. 43

Fig. 44

- Adjust VR777 to re-shape the waveform shown in Figure 45 to that shown in Figure 46. Next, re-adjust VR779 to give 20mV ±10% to the waveform. It may be necessary to repeat adjustments of VR777 and VR779. (This is due to the 2.2Hz W.F. measurement.)
- The above is also performed on TP ⑪ (VR789, VR791) and TP ⑫ (VR801, VR803). Exercise care since these adjustments may cause TP ⑩ to go out of adjustment and necessitate repeat adjustments of TP ⑩ through TP ⑫

Fig. 45

Fig. 46

- Drive gain adjustment**
Utilizing the gain of TP ⑫ as the adjustment criterion, adjust the gains of TP ⑩ and TP ⑪. For TP ⑩, adjust VR784 (1k ohm) to make the heights of "A" and "B" in Figure 48 equal to those of TP ⑫ in Figure 47. At this time, heightening either "A" or "B" will result in a circuit characteristic lowering of the other. For TP ⑪, adjust VR796 to obtain the same result. Lock adjustment may necessitate repeating the 2.2Hz adjustment. (If "B" exceeds 100mV, the motor is defective.)

Fig. 47

Fig. 48

- Lock adjustment**
 - Remove the 670-ohm resistor and 200µF capacitor from TP ⑧.
 - In this state, adjust coarse adjusters VR735 and VR739 to obtain rotation of approximately 33-1/3 and 45 rpm. Connect the probes of a dual beam/trace oscilloscope (2 msec/div) to TP ⑦ and TP ⑨ then externally trigger the scope with signals from TP ⑨. Staying within the -6Hz (min) quartz lock frequency range, adjust VR735 and VR739 until the deviation of each pulse at TP ⑦ is within ± 0.2 msec as shown in Figure 49.

Fig. 49

5-(5) Rotation Adjustment

D. Quick stop adjustment

- With the turntable mounting two 30-cm LP records rotating at 33-1/3 rpm, depress the stop button, then adjust VR647 until the turntable stops without any reverse movement.
- Set the turntable to 45 rpm and mount a 30-cm LP record (approx. 200g), then adjust in the same manner using VR646.
- Confirm that the turntable without a record and running at 33-1/3 or 45 rpm is stopped by the quick stop after slight forward movement.

5-(3) N-time Counter Adjustment

Connect the output leads from a low frequency oscillator to the 6th and 7th terminals of P ⑨. Connect the probe of an oscilloscope to TP ②, then observe the waveform.

- Set the oscillator frequency to 85Hz and adjust VR685 until the waveform displayed on the scope is stable.
- Then, increase the oscillator frequency which confirming that it causes the lock frequency from the oscillator on the PCB to vary accordingly.

Note: When performing this adjustment, disconnect P ⑩ from the motor.

Fig. 50

5-(4) TDC-7 Oscillation Frequency Adjustment

Connect a frequency counter with 7 or more digit reading to TP ⑨ and set the 1Hz control to the "0" point at 33-1/3 rpm, then turn trimmer 50pF of C802 on TDC-7 to adjust the frequency to 100.0000 ±0.0001Hz.

A. Reason for adjusting rotation

This equipment employing the quartz-lock servo method ensures constant rotation of the turntable at either 33.33 or 45.00 rpm. However, a 1Hz pitch control is provided for the following reason.

At present, the frequency of standard tone "A'" is specified as 440Hz and is the basic tone in all musical instruments and music, thus providing the basis for tuning of an orchestra etc.

In spite of this, depending on the characteristic of an orchestra or objectivity of the conductor, the basic frequency often deviates from 440Hz within the range of ±6Hz. On the other hand, the "A'" tones in home use pianos are all tuned at 440Hz. Therefore, when practicing on a piano with accompaniment from a record of a performance of the above type of orchestra, pitch control is required. Pitch control also permits comparison of a recorded orchestration with another of the same music but in different tune, thus providing new enjoyment through listening to the difference in musical philosophy of different orchestras.

B. RPM indication

Since a 4-digit digital counter to indicate turntable rpm is provided, precise monitoring of the revolving speed of the quartz-lock turntable can be performed at any time.

After the power switch is turned on and the rpm selection button is set to either 33-1/3 or 45, the unit reaches to the rated speed within a superb 0.6 seconds, and 1.5 seconds after the rpm selection button is set, the digital counter ensures correct indications by counting 2 additional seconds before starting to display the rpm. Therefore, it takes a total of 3 seconds after the start for the counter to start providing an indication. The counter counts down to the 3rd digit to the right of the decimal point and the least significant 3rd digit is rounded off for indication. However, due to a characteristic of the circuit, if the 3rd digit to the right of the decimal point is either "0" or "9", the indication may be somewhat different from that shown on the table in Figure 51.

C. Fine adjust RPM indication

If fine rpm adjustment is performed, the digital indication will become as shown on the following table.

Pitch Speed	+6 Hz	+5	+4	+3	+2	+1	0	-1	-2	-3	-4	-5	-6 Hz
33	33.79	33.71	33.64	33.56	33.48	33.41	33.33	33.25	33.18	33.10	33.03	32.96	32.88
45	45.62	45.51	45.41	45.30	45.20	45.10	45.00	44.89	44.79	44.69	44.59	44.49	44.39

Fig. 51

6. Connection Diagram

6-(1) Ground Connection

Fig. 52

- Connect the ground terminal on the unit and the ground terminal on the amplifier.
- Connect the attached accessory ground wire to the ground terminal on the unit.
- Connect the other end of the ground wire to the ground terminal on the amplifier.

6-(2) P.C.Board Ass'y Connection

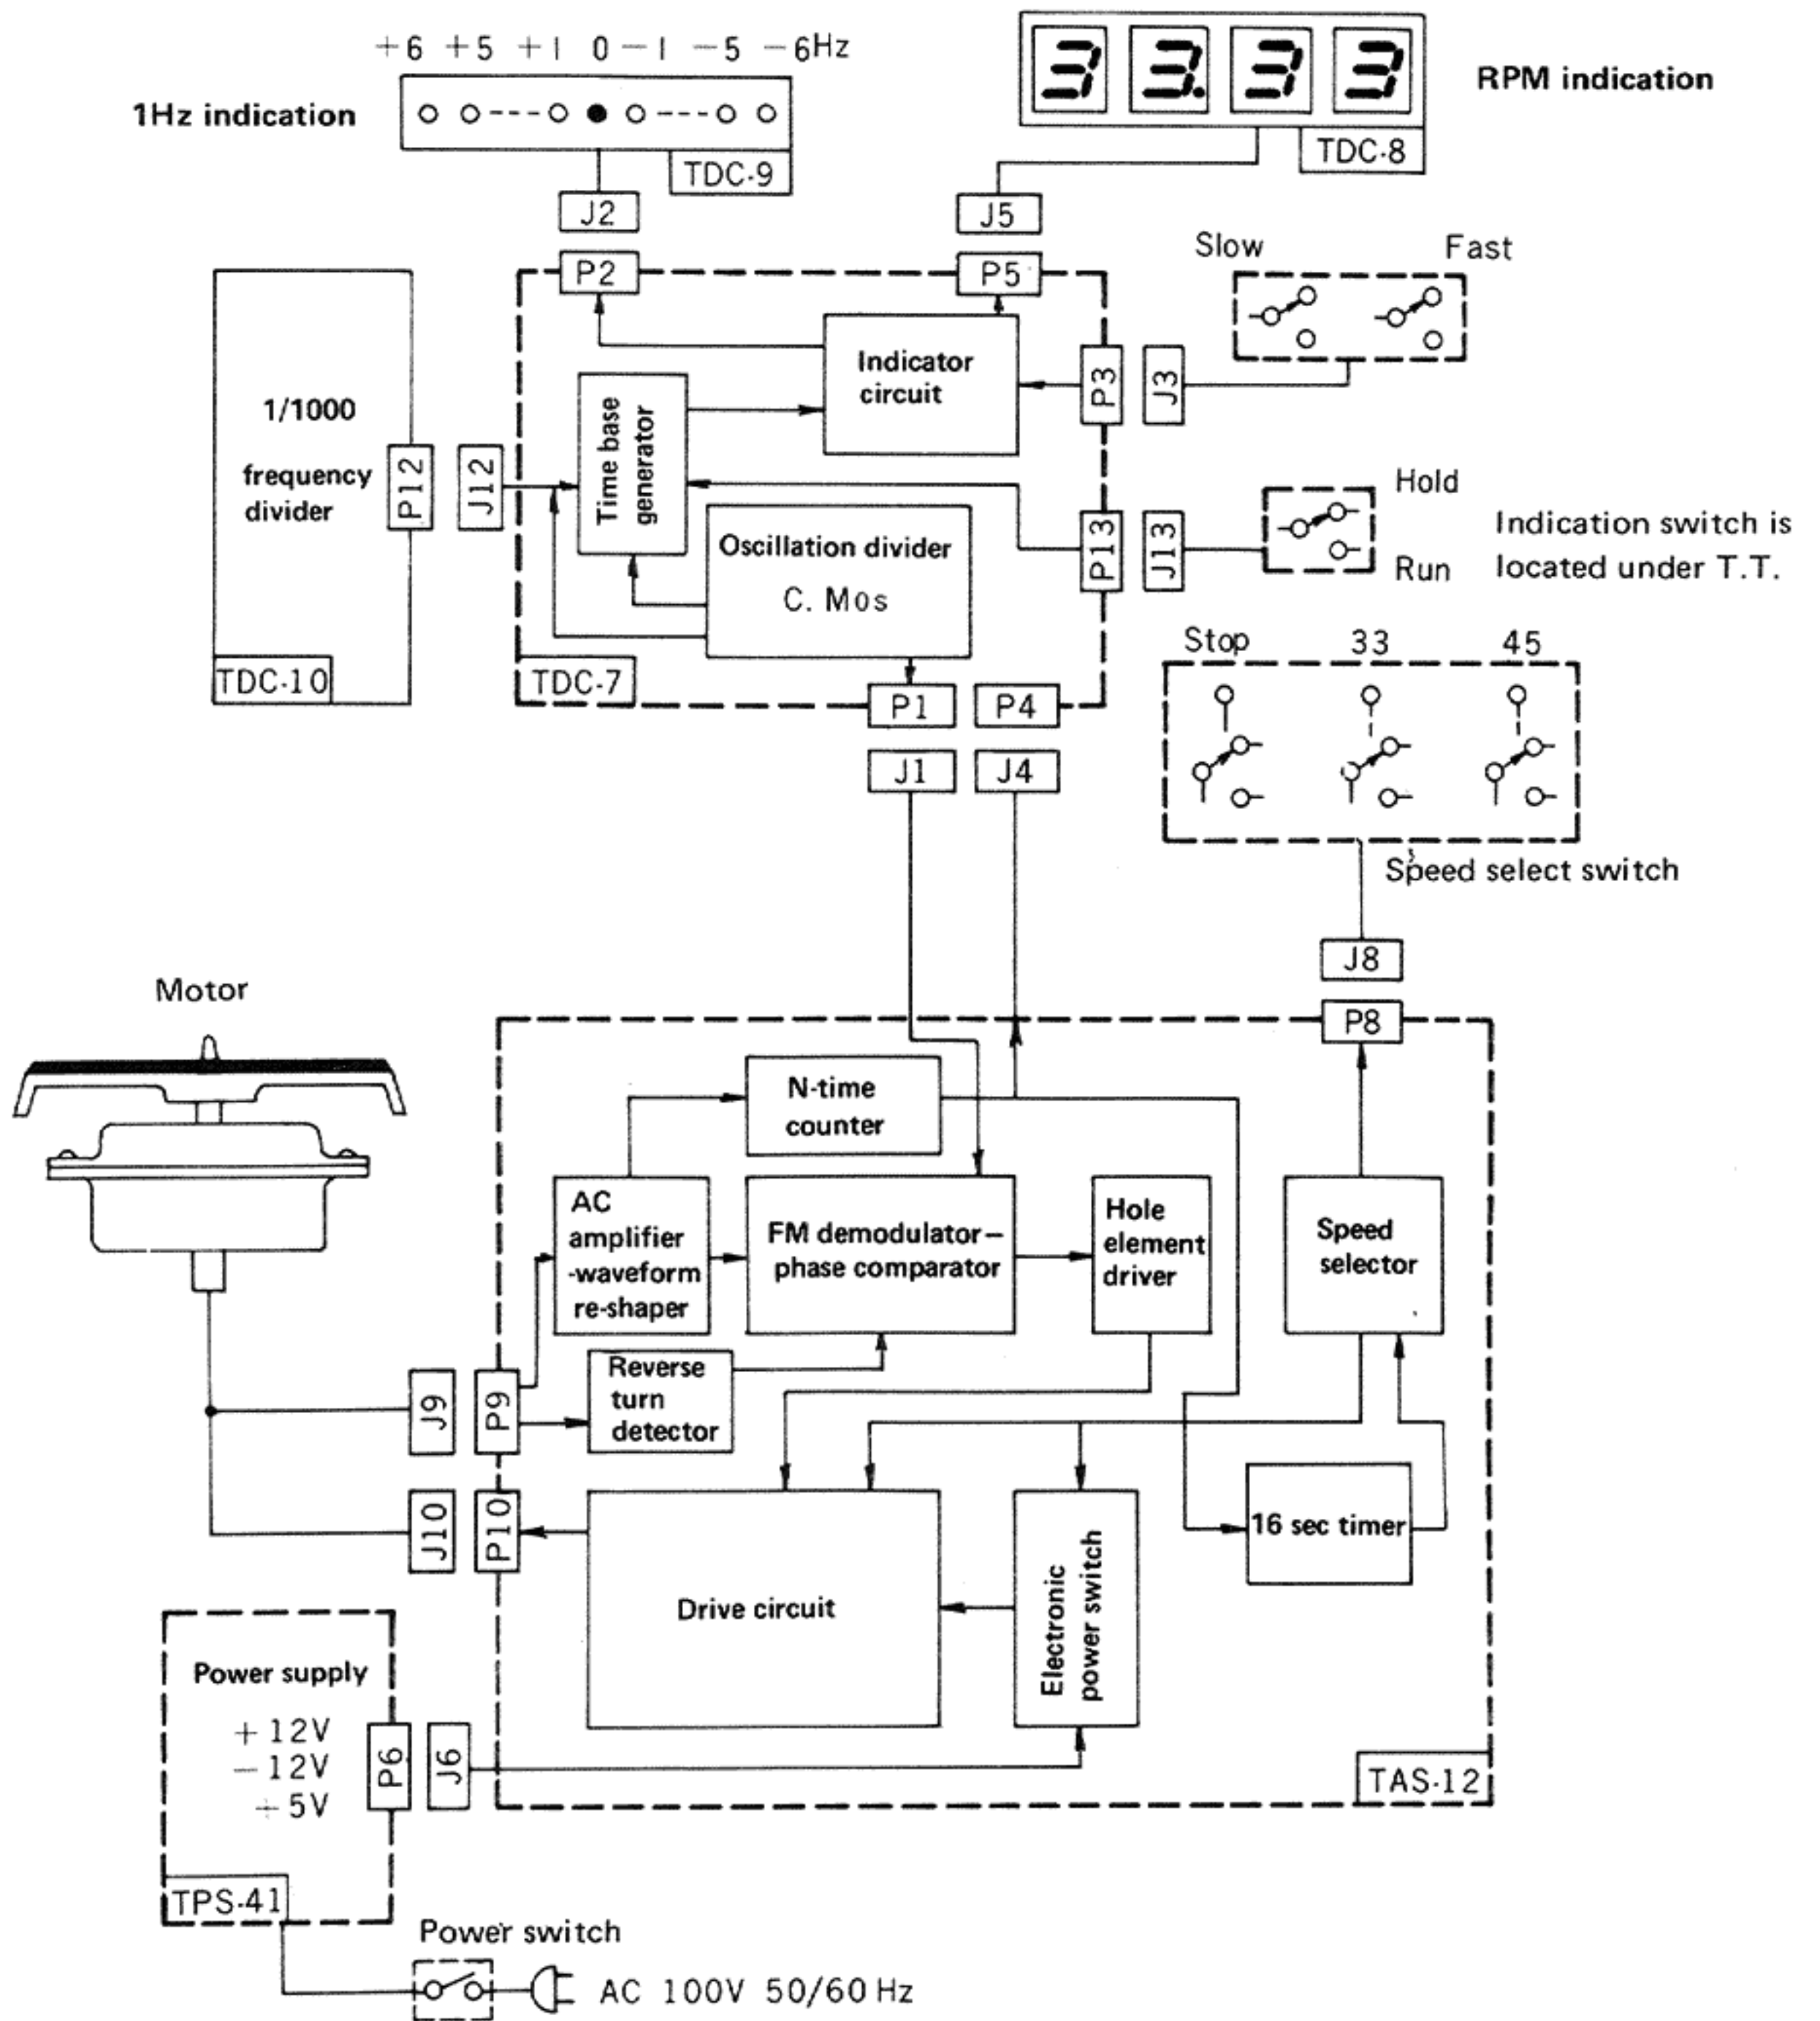

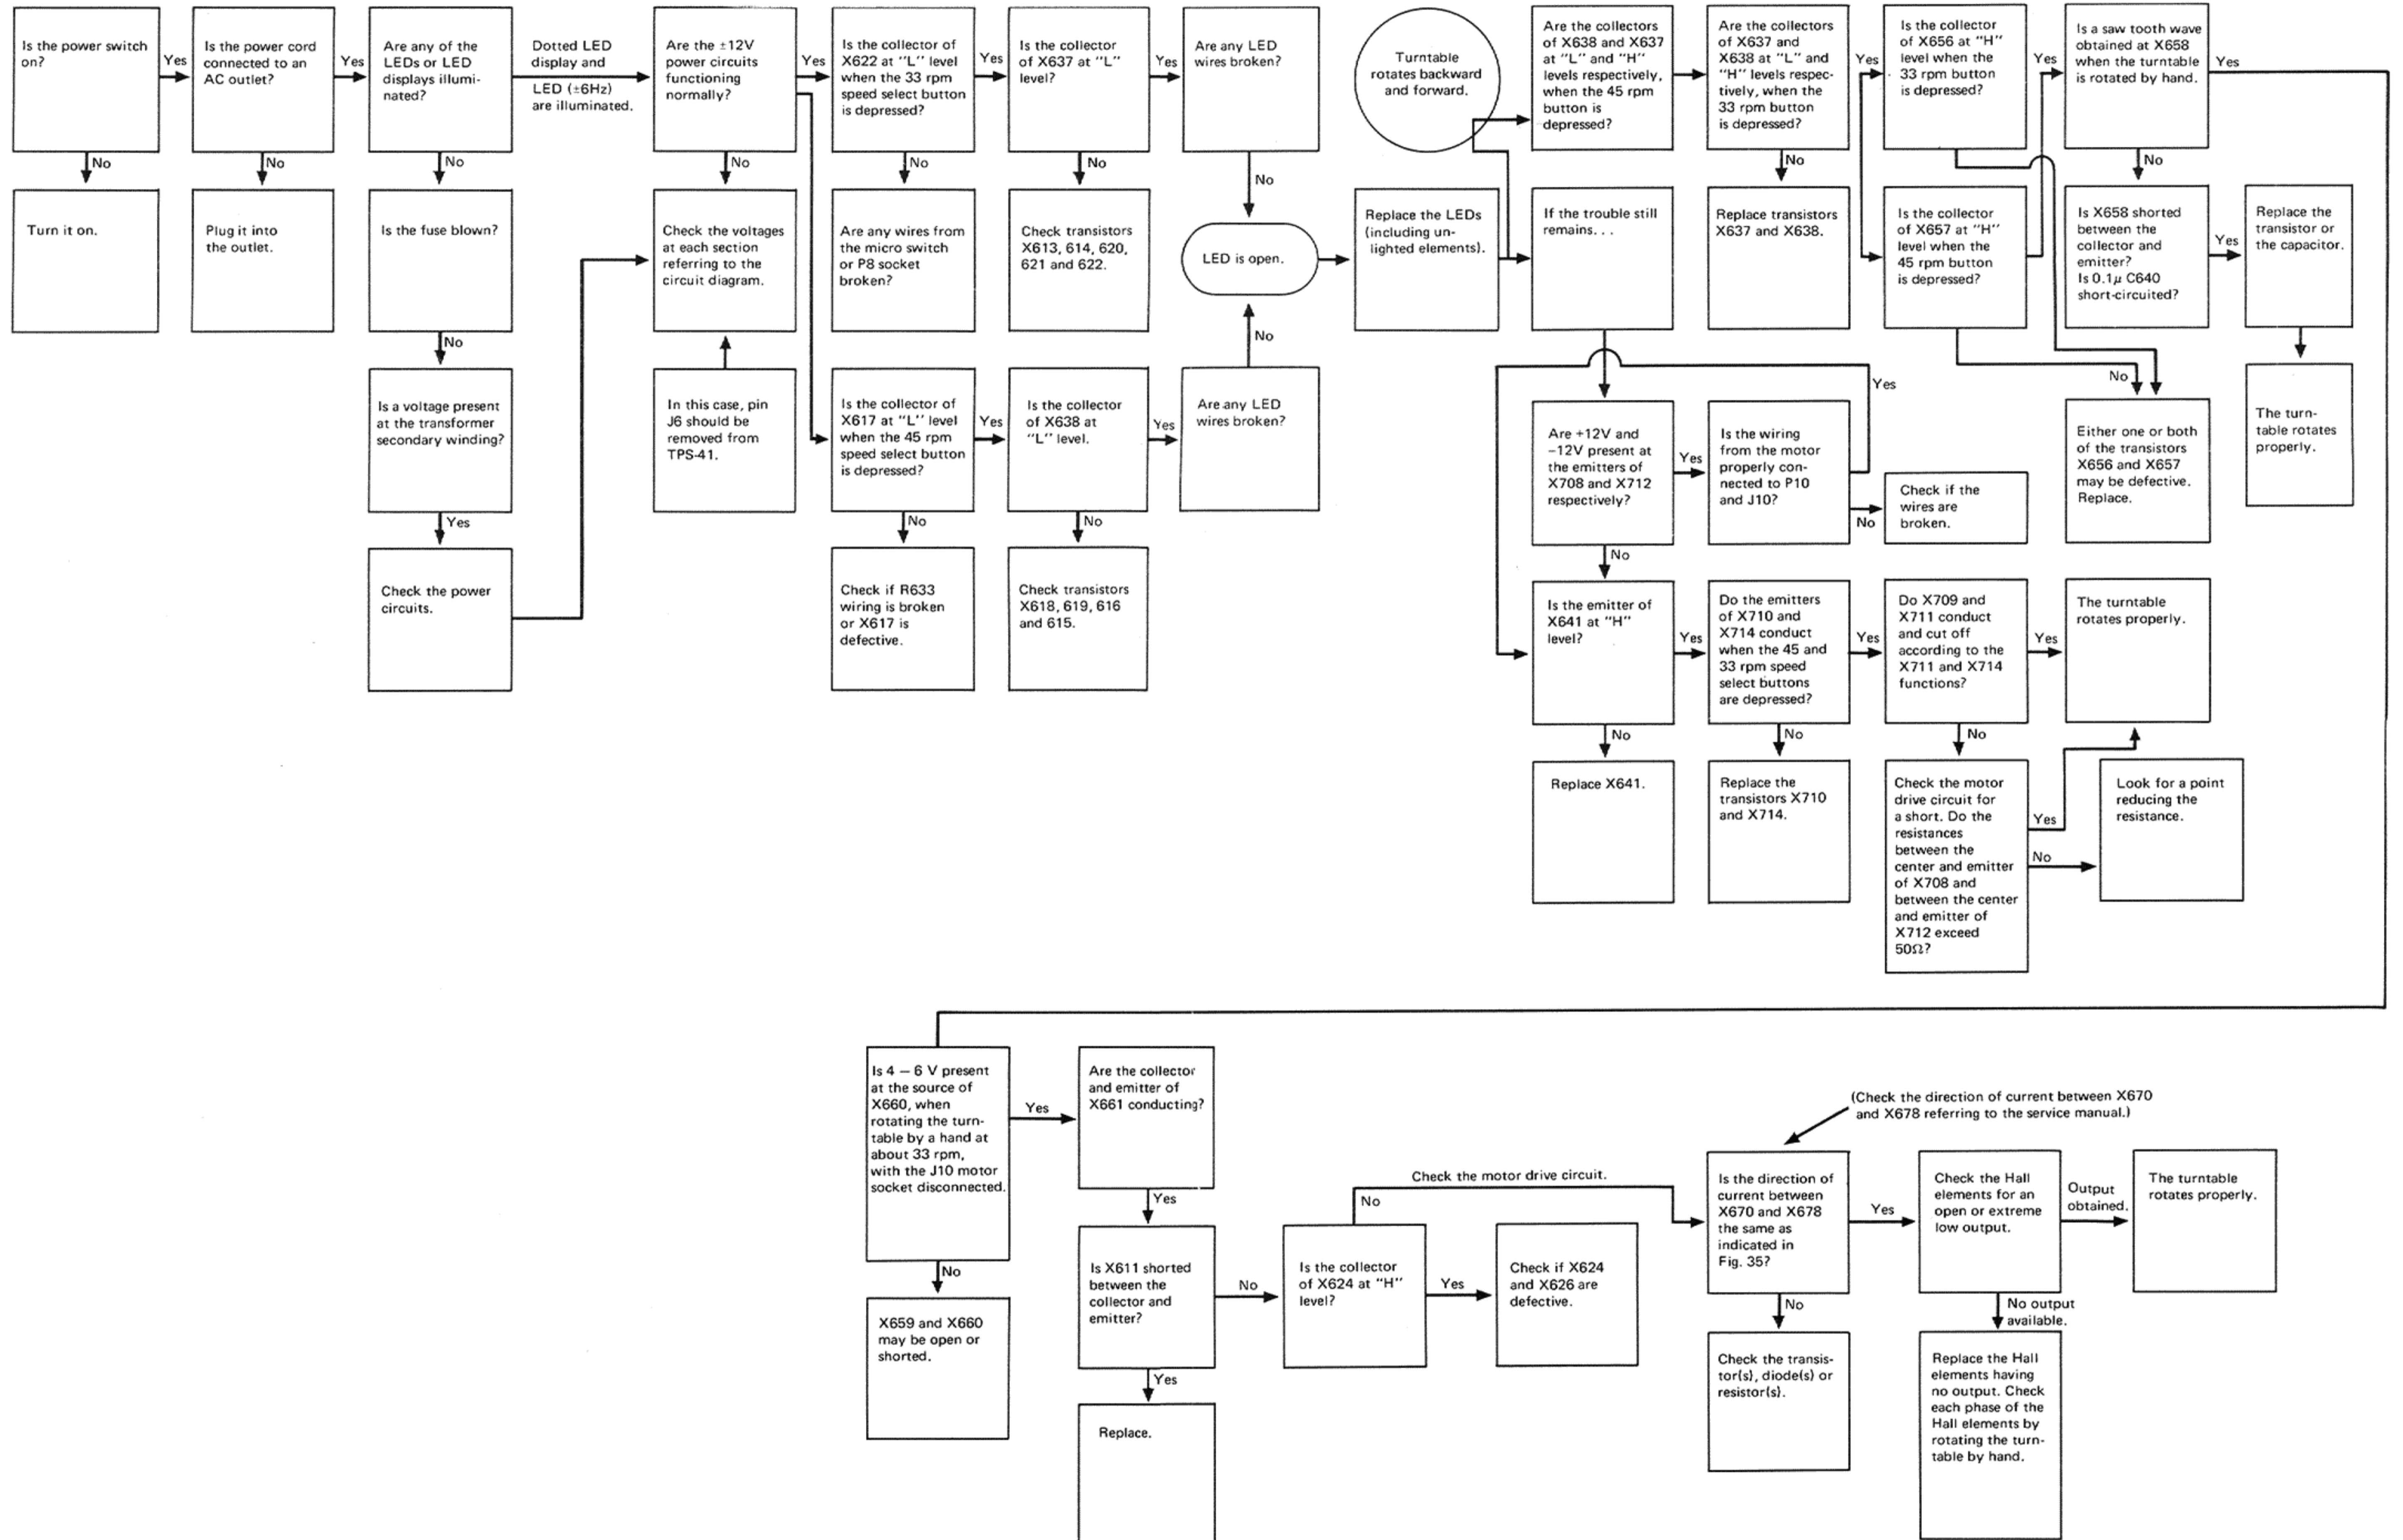

Fig. 53

7. Lubrication

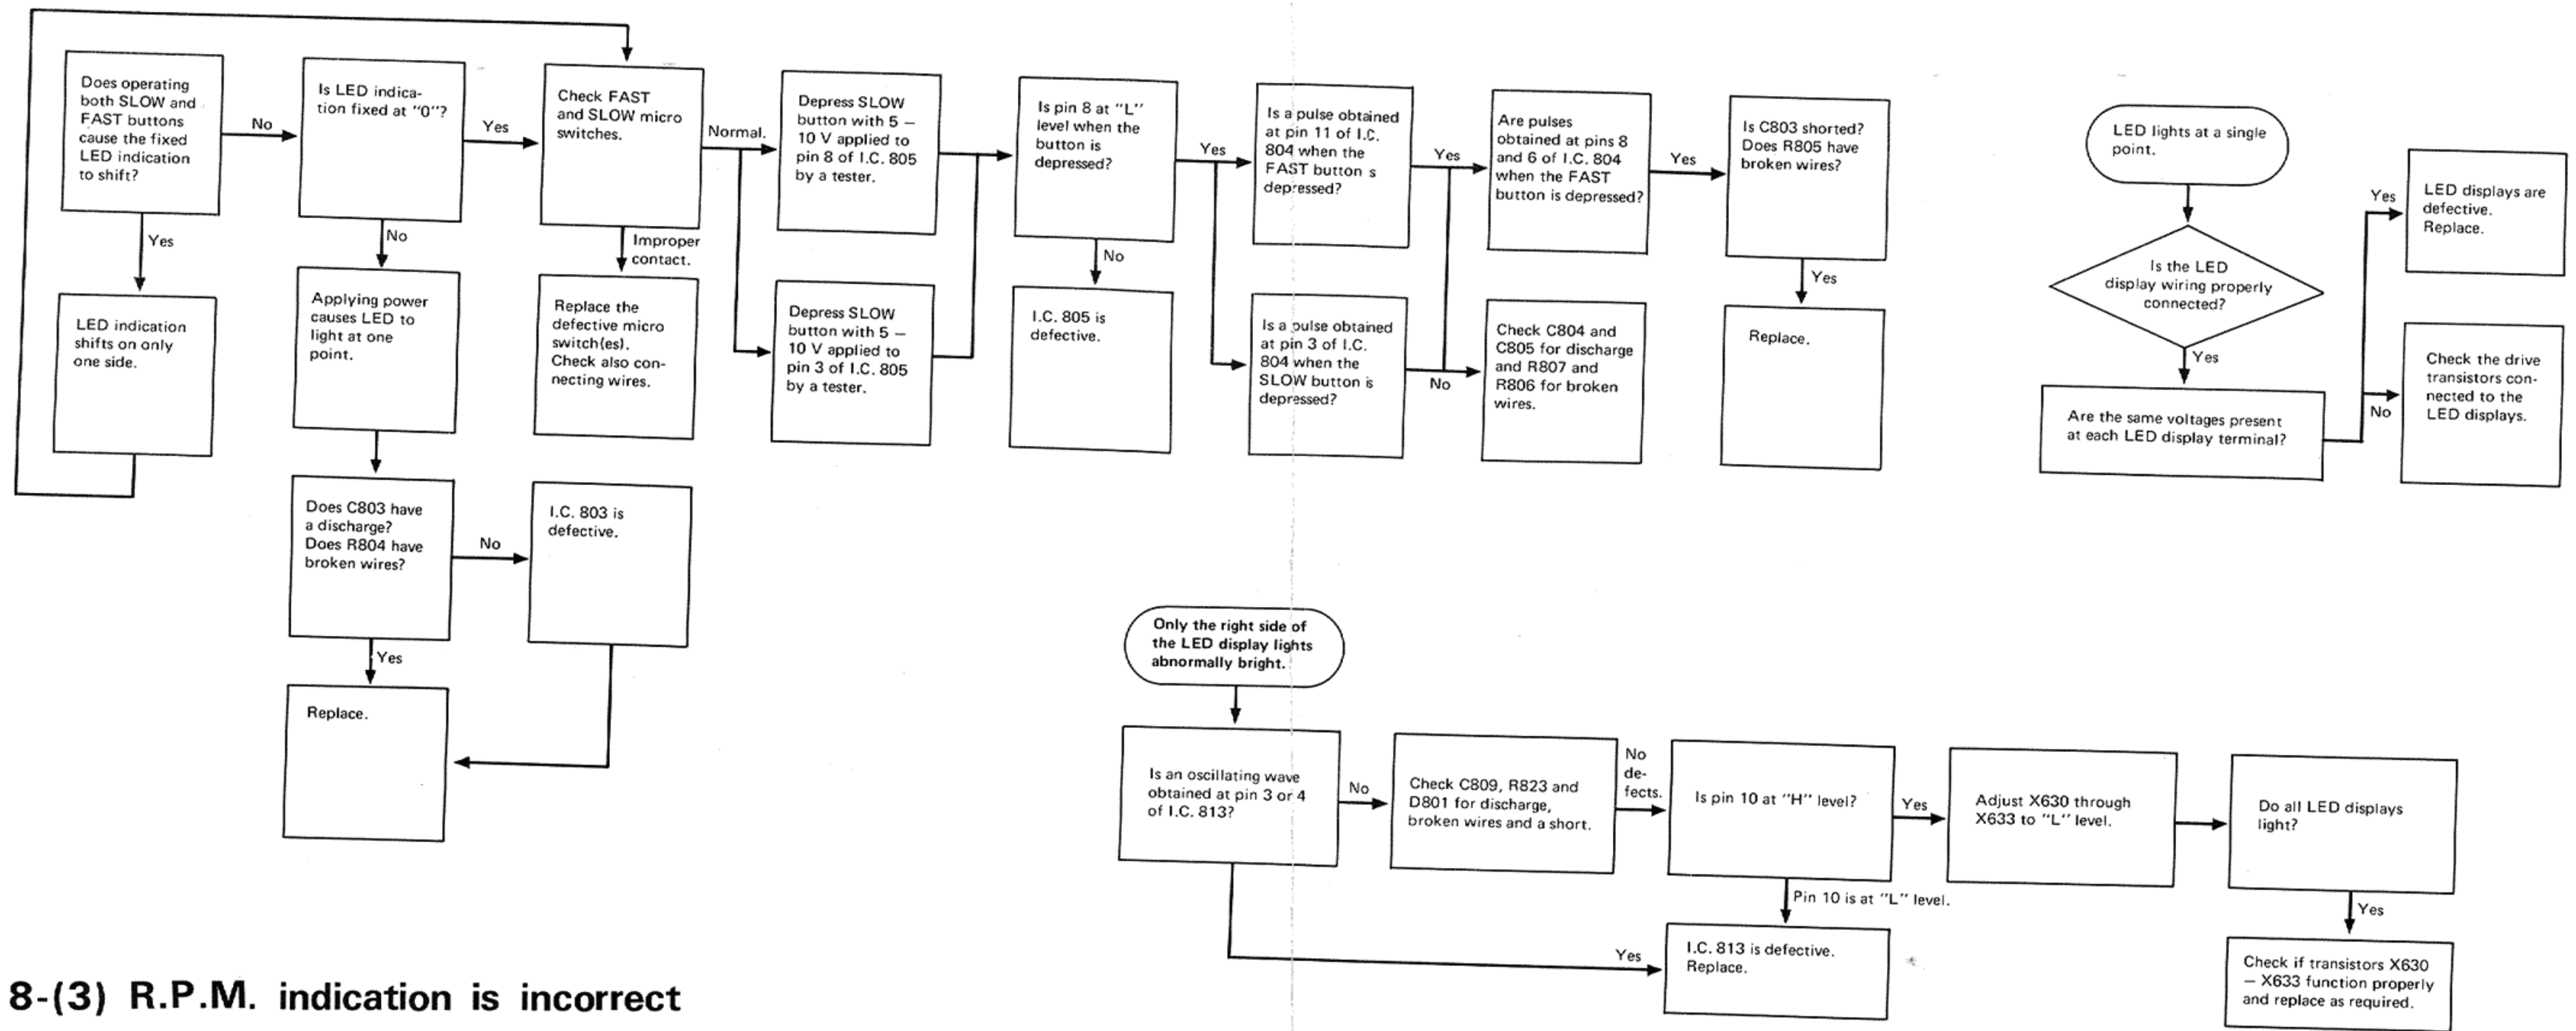

The direct drive motor used in the unit does not require lubrication.

8. Troubleshootings

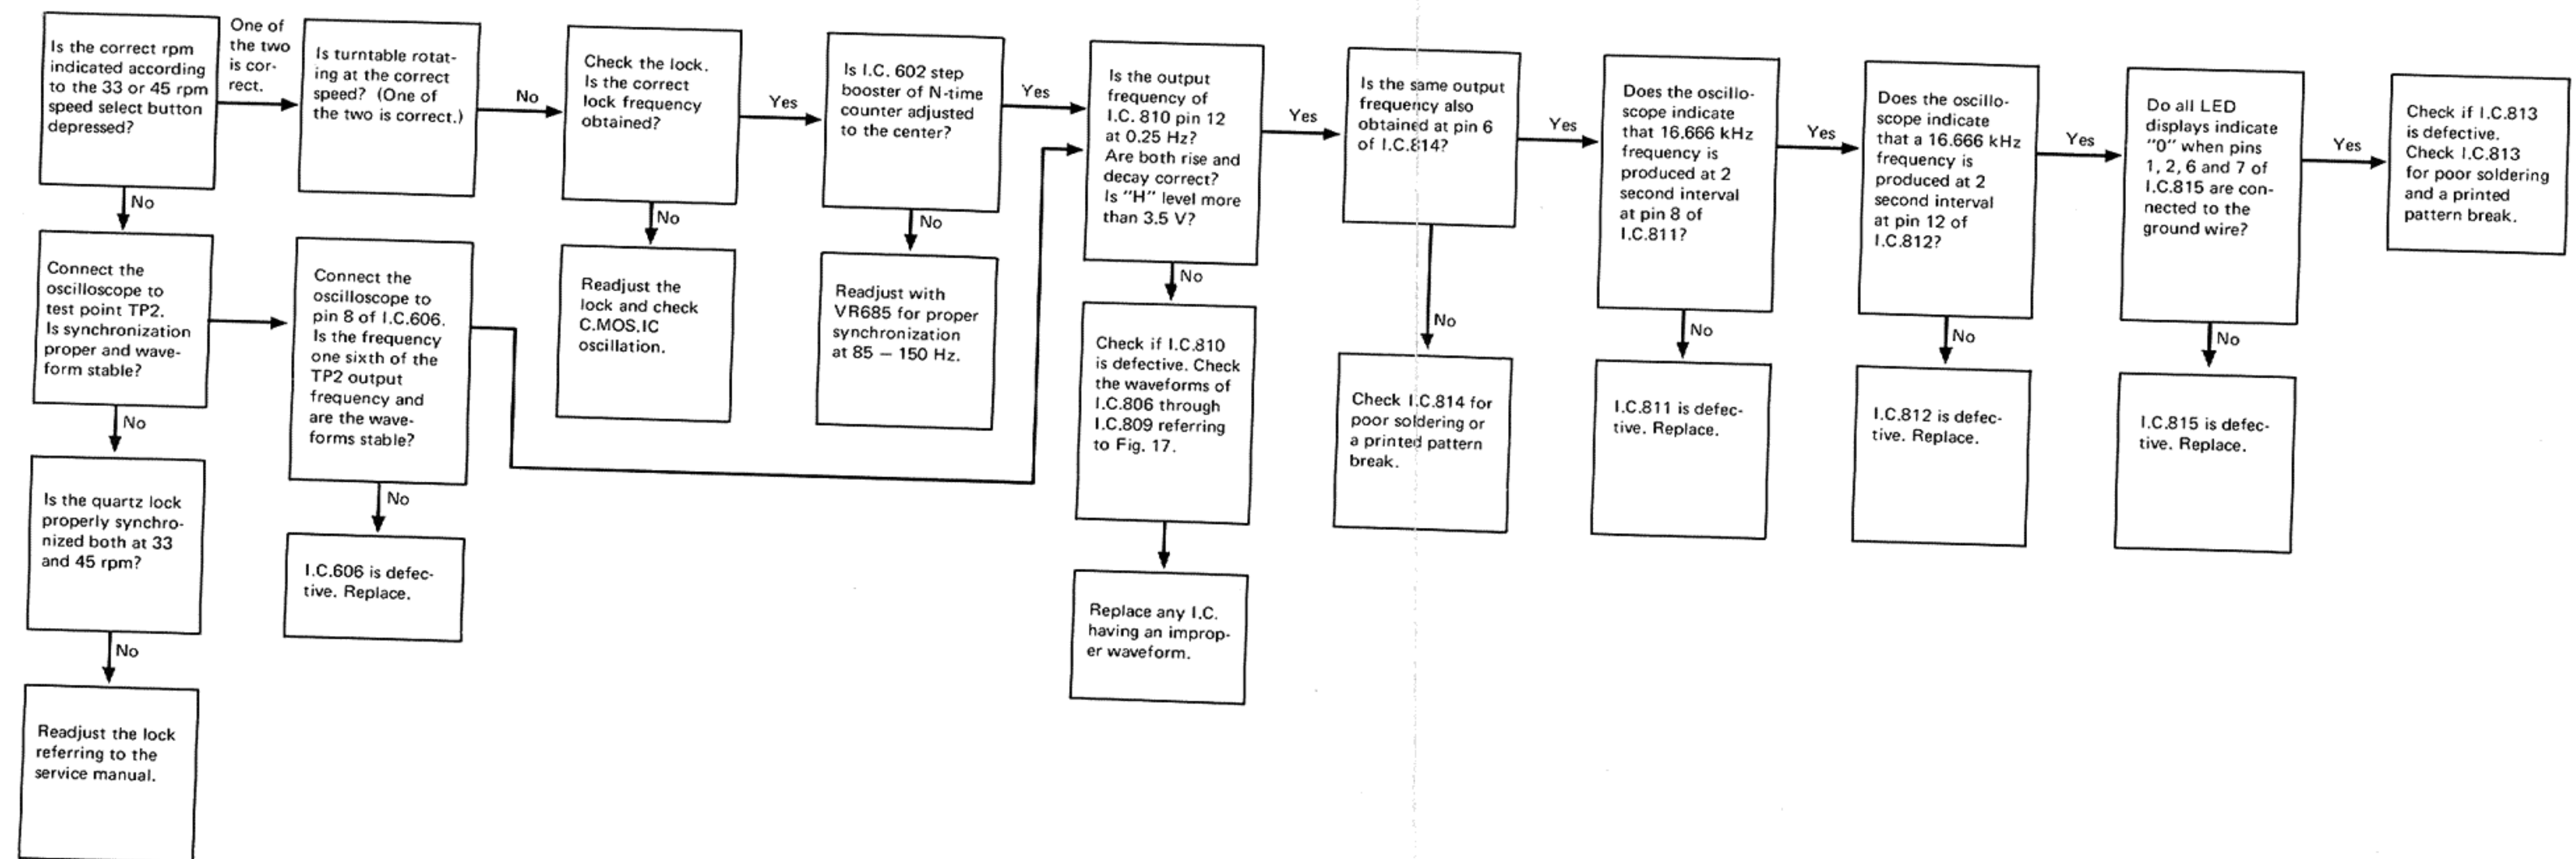

8-(1) Turntable does not rotate

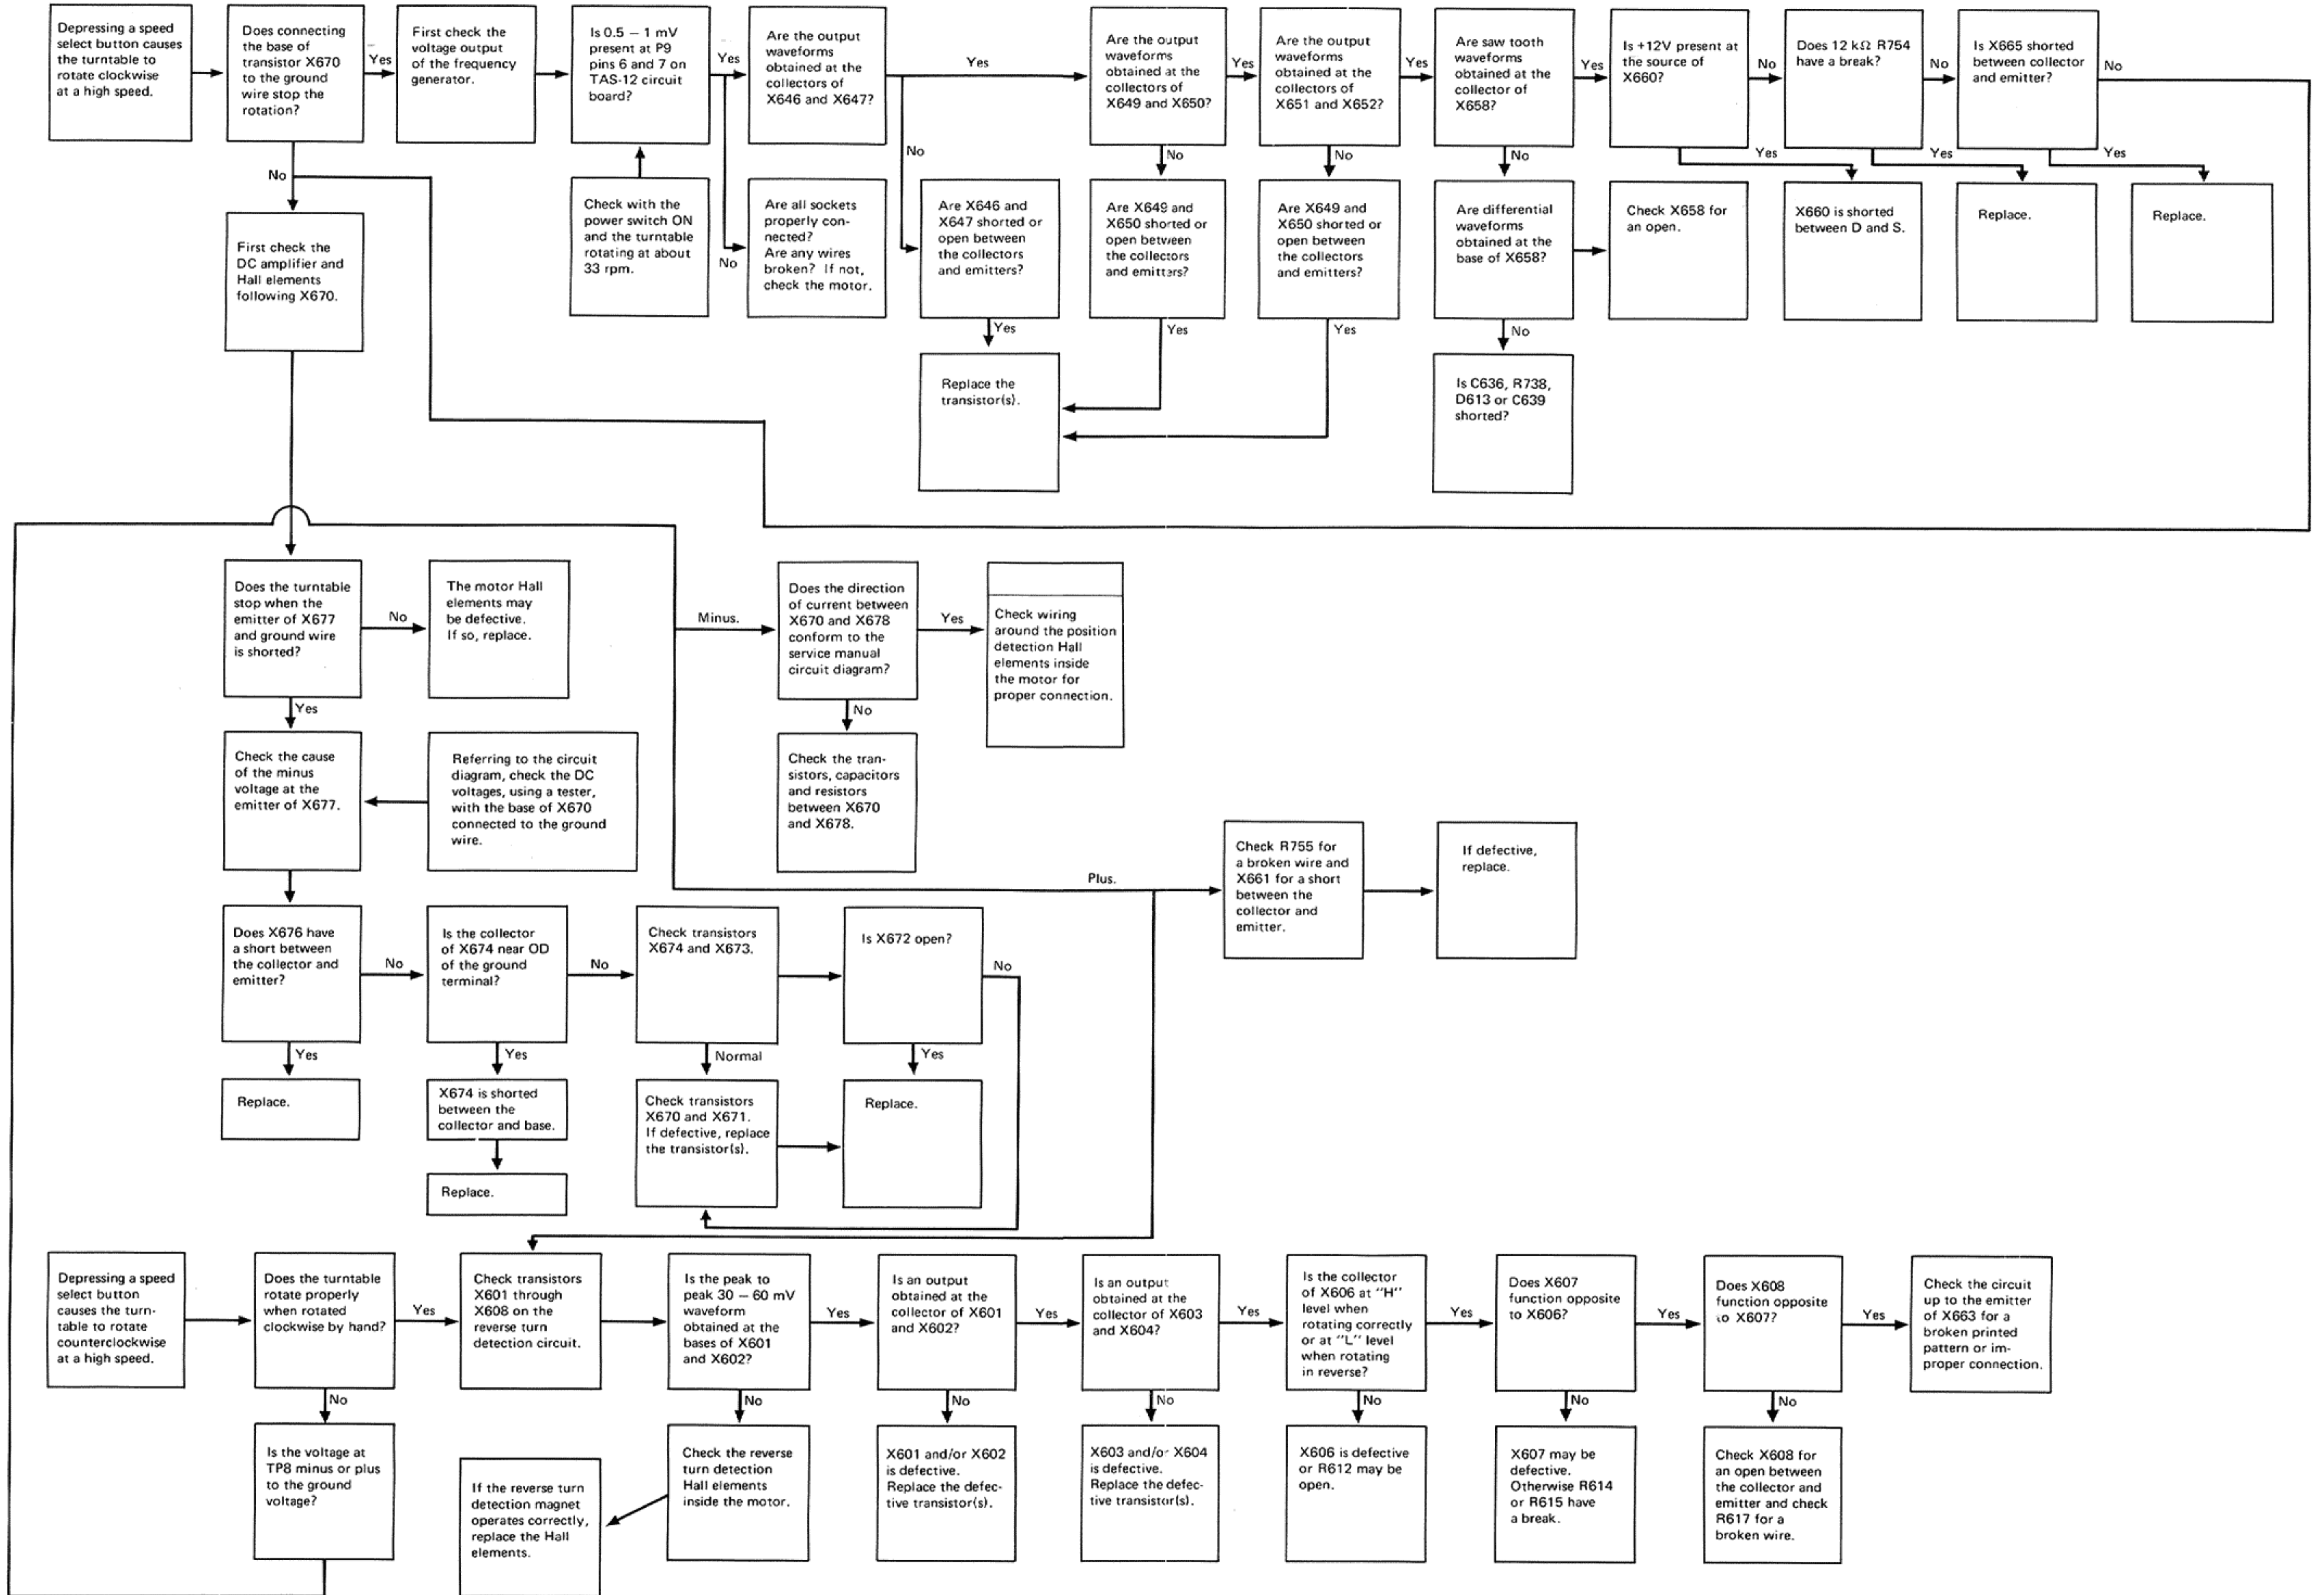

8-(2) The 1Hz step LED indication is fixed at one point and cannot be controlled

8-(3) R.P.M. indication is incorrect

8-(4) Turntable rotates at high speed

- Metal film resistor
QRX148F.
- Glazed metal variable resistor
QVZ3501.
- Polycarbonate capacitor
QEZ0050-104
- Low leak chemical capacitor
QEB41HM DC 50 V
- Non porous chemical capacitor
QEZ0046-106 DC 50 V

Note:
 Transistors enclosed by the broken lines should be
 from the same lot to ensure equal performance.

- Special precautions
- Power on/off
Do not turn the power on until all required connections
between circuits have been completed. Do not insert or
remove plugs while the power is on.
 - Handling of C.M.O.S.
C.M.O.S. IC801, IC813 and IC602 are very sensitive. There-
fore, care should be exercised to prevent contact with other
components in replacement, or current leaks may result.
Maintain the same voltage level for all elements.
