KOLSTER BRANDES KR019 REGENTONE TR419

A.M./F.M. Transistor Portable Radio Receivers

EMPLYING twelve transistors and five diodes, K.B. KR019 and Regentone TR419 are three-waveband a.m./f.m. radio receivers which are fitted with an identical chassis. They are powered by a 6V battery (four 1.5V cells) and, using a push-pull output stage, provide 300mW audio power to a 3½ in. loudspeaker.

Ferrite rod and telescopic aerials are incorporated in the receiver and a socket is provided for the connection of a car type aerial. A second socket provides an output which can be fed to an earphone, with automatic muting of the internal loudspeaker.

Waveband ranges are 184-586m (m.w.),

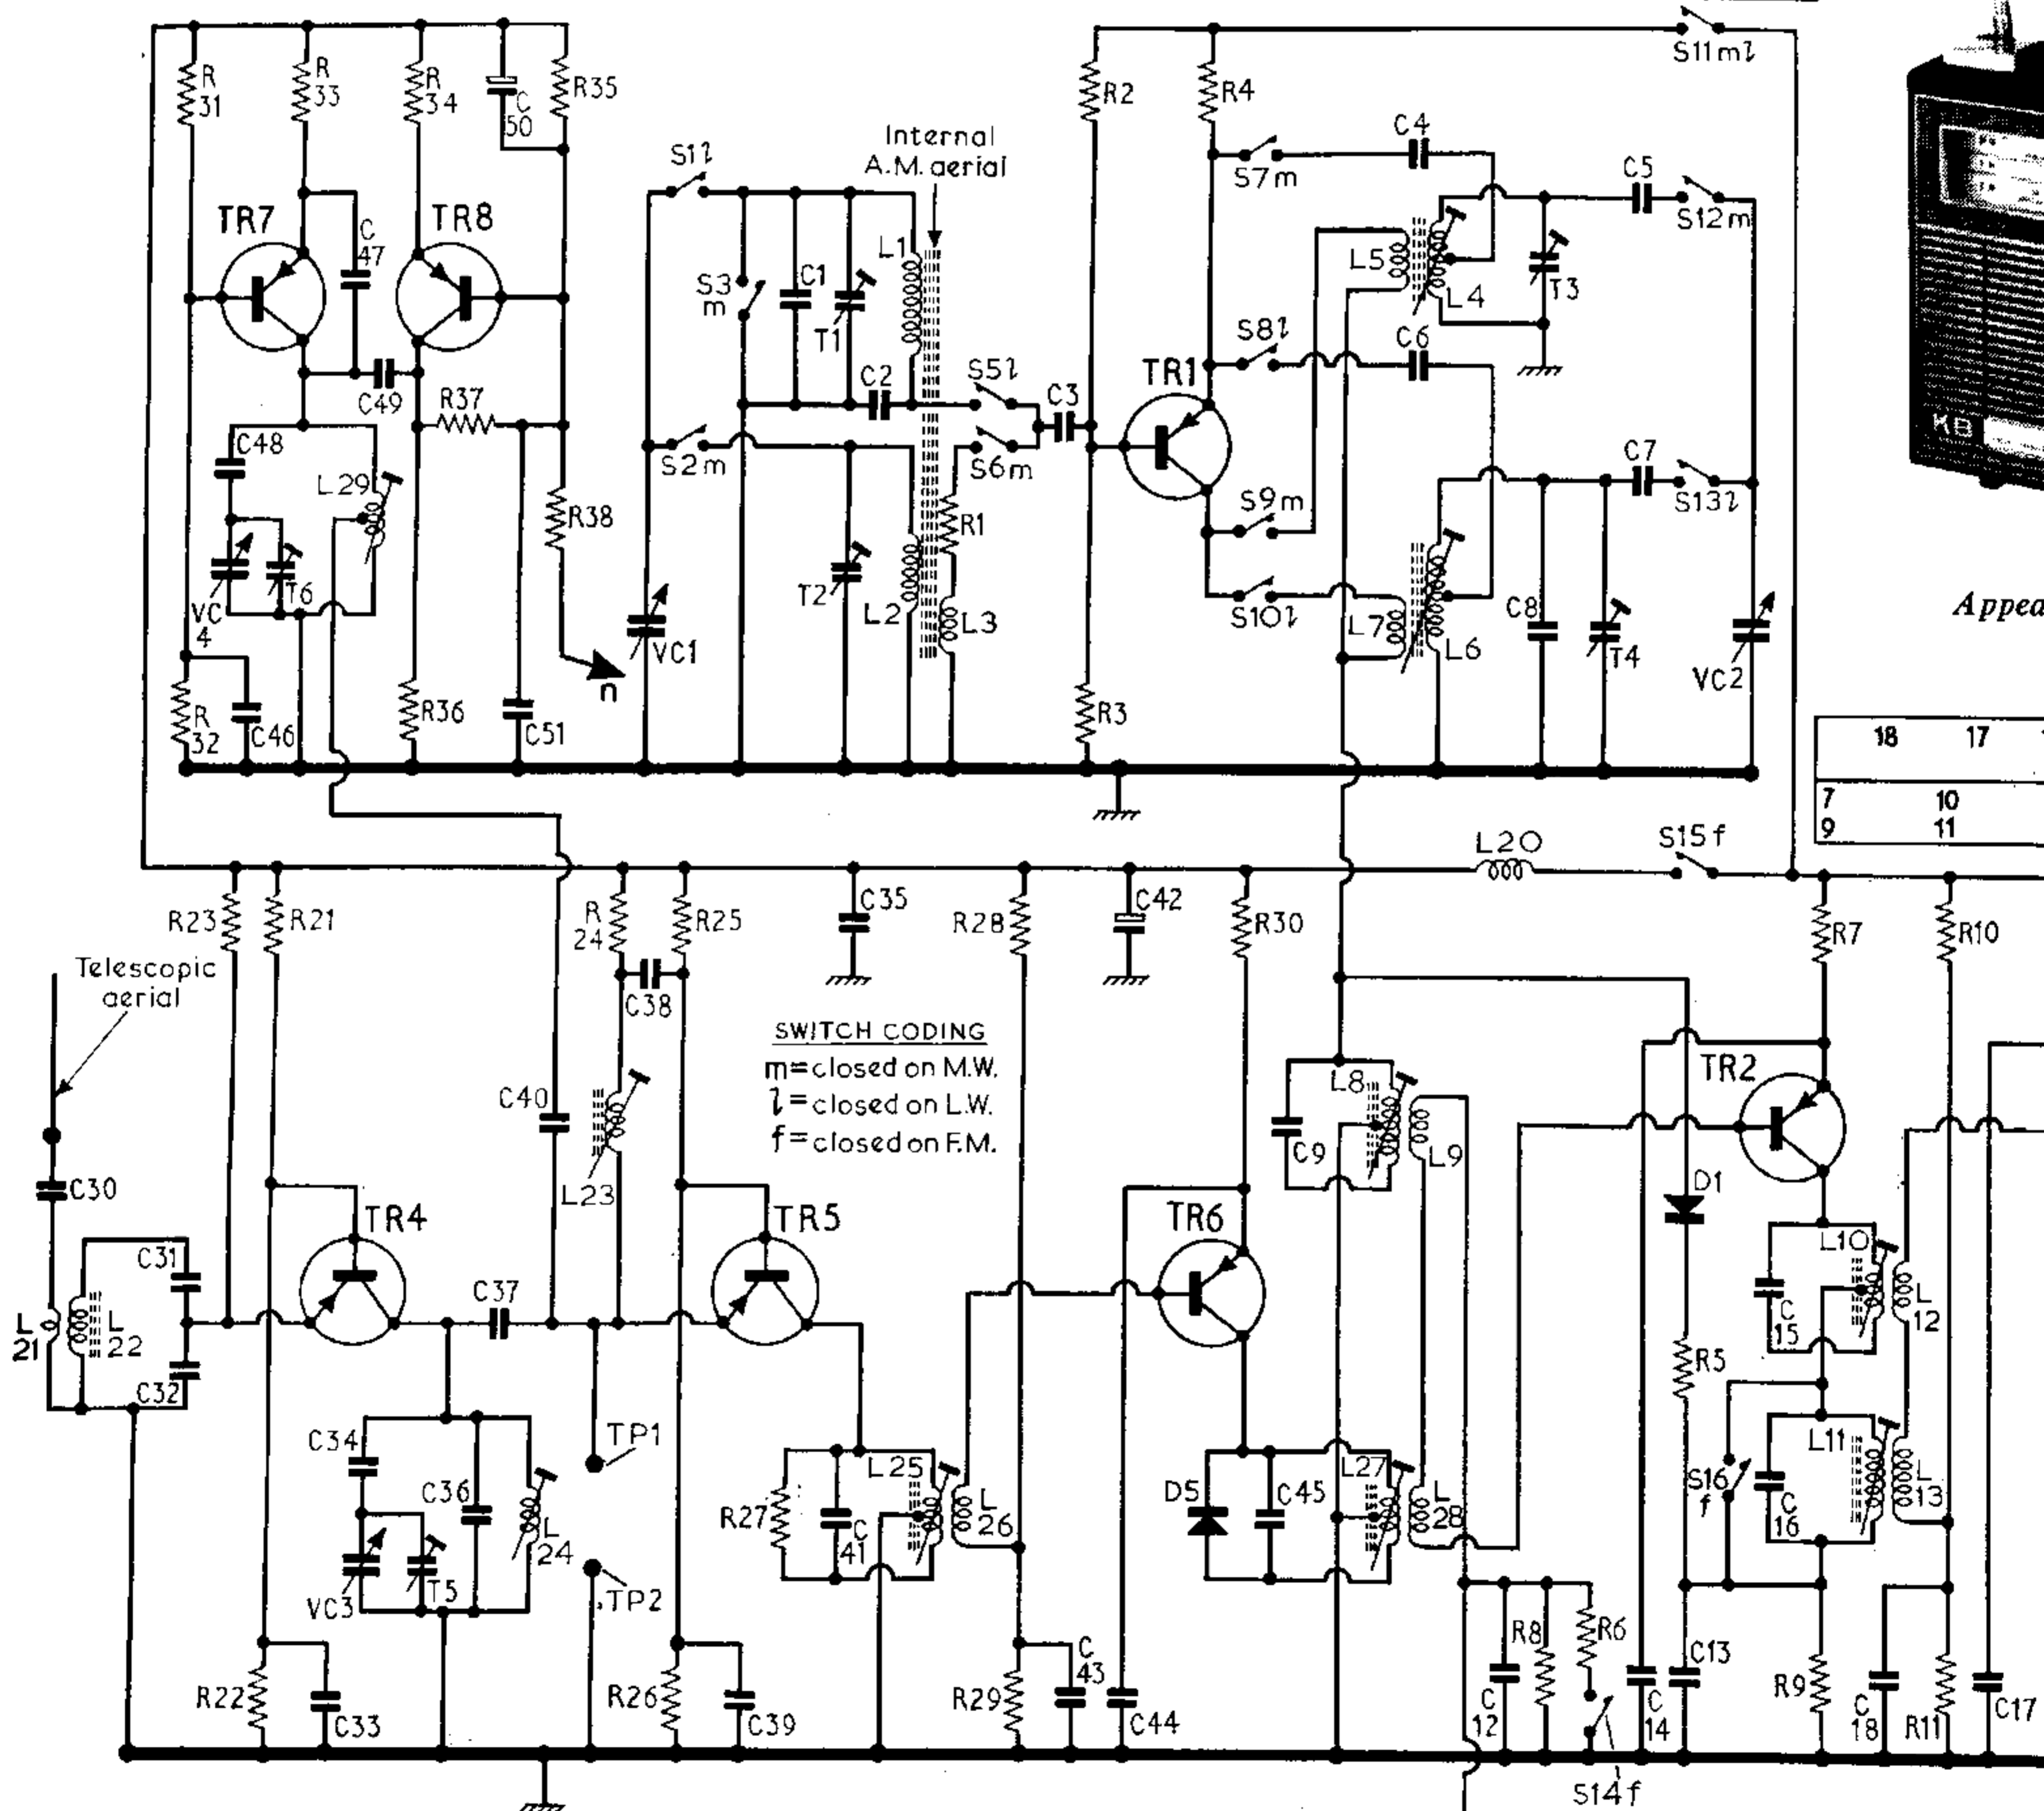

1,091-2,174m. (l.w.) and 86.5-105.1Mc/s (f.m.) Battery consumption is 9mA quiescent and 110mA for 300mW output.

TRANSISTOR ANALYSIS

Transistor voltages quoted in the table in col. 6 were taken from information

Circuit diagram of the chassis employed in K.B.KR019 and Regentone TR419 portable radio receivers. On f.m., separate oscillator and mixer stages are used (TR7 and TR5) with an additional transistor (TR8) providing automatic frequency control of the oscillator

Appearance of our sample receiver K.B.KR019

Component-side view of the chassis showing the location of components on the r.f. and a.f. printed panels. R13 and C20, shown in broken line in location reference B3, are wired on the foil side. The connections of these two components should be checked as described in col. 6

Continued from overleaf—
supplied by the makers. They were measured, except where stated otherwise, with the receiver switched to f.m. and are positive with respect to chassis.

CIRCUIT DESCRIPTION

F.M. signals from the telescopic aerial are coupled via the wideband input transformer L21, L22 to the emitter of TR4 which operates as an earthed base r.f. amplifier. The collector circuit L24 is tuned together with the oscillator coil L29 by ganged capacitors VC3 and VC4. L23 shunts the input to TR5 with a low impedance at 10.7Mc/s. TR5 operates as an earthed base mixer stage with r.f. signals coupled to its emitter via C37 together with oscillator voltage from the oscillator stage TR7 via C40.

The resultant 10.7Mc/s i.f. signals present in TR5 collector circuit are selected by the tuned i.f. transformer primary L25 and coupled by the secondary L26 to a three-stage i.f. amplifier comprising TR6, TR2 and TR3. Limiter diode D5 prevents overloading of the i.f. channel on strong signals.

Amplified output from TR3 is fed to the f.m. ratio detector comprising discriminator transformer L14, L15, L17, L18 and diodes D3, D4. Audio output from the detector is de-emphasised by components R17, C28 and fed via S17 to the volume control R39.

The d.c. voltage developed at the ratio detector, due to the f.m. signal, is fed via R38 to the base of TR8. This voltage determines the degree of conduction of TR8 and thus the effect of C49 across the oscillator tuned circuit L29. By this means the oscillator is retuned, providing automatic frequency control.

On a.m., signals induced in the ferrite rod aerial are coupled to the base of TR1 which operates as a self-oscillating mixer with separate aerial and oscillator coils for either waveband. I.f. output from TR1 is passed via L8 and L9 to a two-stage i.f. amplifier TR2 and TR3 and then to the detector diode D2. The d.c. voltage which is developed across the diode load and volume control R39 is fed via R18 to the base of TR2 as a.g.c. bias.

The audio section comprises three stages, TR9, TR10 and the push-pull output pair TR11 and TR12. Negative feedback is applied to TR10 emitter via R56, C60 and C58 while the output stage bias is temperature stabilised by thermistor TH1.

CIRCUIT ALIGNMENT

Equipment Required.—An a.m./f.m. signal generator covering the range 140-1,630kc/s a.m., modulated 30 per cent at 1,000c/s, and 10.7-105Mc/s f.m., an audio output meter with an impedance to match 8Ω; a shielded r.f. coupling coil (85 turns of enamelled copper wire on a 2 in. diameter former);

a 5,000pF capacitor and suitable trimming tools.

During alignment, the signal input level should be adjusted to maintain receiver output of approximately 50mW.

A.M. CIRCUITS

- 1.—Connect the audio output meter to the receiver via the earphone socket using the correct type of plug. Connect the signal generator to the coupling coil and place the coil co-axially with the ferrite rod, five inches from the m.w. winding.
- 2.—Set the volume control at maximum and the tone control at maximum high frequency response. Turn the tuning gang to the fully closed position and check that the cursor lines up with the "L" of "Light" on the f.m. scale.
- 3.—Switch receiver to m.w. and fully open the tuning gang. Feed in a 470kc/s a.m. modulated signal and adjust L16, L11 and L8 for maximum output. Repeat.
- 4.—Fully close the tuning gang. Feed in a 509kc/s signal and adjust L4 for maximum output.
- 5.—Fully open the tuning gang. Feed in a 1,630kc/s signal and adjust T3 for maximum output.
- 6.—Tune receiver to 500m. Feed in a 600kc/s signal and adjust L2 (slide

Drive cord assembly, drawn as seen when the tuning gang is fully open. Full directions for fitting a replacement cord are given under "General Notes"

- former along ferrite rod) for maximum output.
- 7.—Tune receiver to 214m. Feed in a 1,400kc/s signal and adjust T2 for maximum output.
- 8.—Repeat operations 4, 5, 6 and 7.
- 9.—Switch receiver to l.w. and fully close the tuning gang. Feed in a 140kc/s signal and adjust L6 for maximum output.
- 10.—Fully open the tuning gang. Feed in a 270kc/s signal and adjust T4 for maximum output.
- 11.—Tune receiver to 1,875m. Feed in a 160kc/s signal and adjust L1 (slide former along ferrite rod) for maximum output.
- 12.—Tune receiver to 1,200m. Feed in a 250kc/s signal and adjust T1 for maximum output.
- 13.—Repeat operations 9, 10, 11 and 12.

F.M. CIRCUITS

- 1.—Connect the audio output meter to the receiver via the earphone socket using the correct type of plug. Connect the signal generator via a 5,000pF capacitor to the red wire test point.
- 2.—Switch receiver to f.m., turn the volume control to maximum and the tone control to maximum high frequency response.
- 3.—Feed in a 10.7Mc/s signal, f.m. deviation ± 25 kc/s at 1,000c/s, and adjust L15, L10, L27 and L25 for maximum output. Adjust L23 for minimum output.
- 4.—Switch the signal generator to a.m. modulation, 30 per cent at 1,000c/s and adjust L18 for minimum output.
- 5.—Repeat operations 3 and 4.
- 6.—Retract the telescopic aerial fully and connect the signal generator to the car aerial socket.
- 7.—Fully close the tuning gang. Feed in an 87Mc/s f.m. signal and manipulate L29 (expand or contract the turns) for maximum output.
- 8.—Fully open the tuning gang. Feed in 105Mc/s signal and adjust T6 for maximum output.
- 9.—Tune receiver to 90Mc/s. Feed in a 90Mc/s signal and manipulate L24 for maximum output.
- 10.—Tune receiver to 104Mc/s. Feed in a 104Mc/s signal and adjust T5 for maximum output.

11.—Repeat operations 7, 8, 9 and 10.

GENERAL NOTES

Dismantling.—To remove the chassis from the case, open the rear flap and take out the batteries and battery container.

Pull off the front control knobs.

Take out five chassis fixing screws. These are located as follows: one at either end of the battery bracket, one below L16, L19 i.f. can, one in the top left-hand corner of the chassis and one on the right-hand side of the chassis immediately above the audio panel and behind the telescopic aerial.

Unsolder the leads from the car aerial socket.

The chassis and battery bracket can now be eased out from under the telescopic aerial rod to the extent of the speaker leads.

Drive Cord Replacement.—A diagram of the drive cord system appears at top of page.

To fit a replacement, fully open the tuning gang. Pass one end of the new cord through the hole A on the drive drum B, leaving approximately 1½ in. of cord protruding on the top side of the drive drum.

Wind the other end of the cord 2½ turns clockwise round the drive drum then route the cord over pulleys C and D and the tension arm E. Pass the cord over the drive drum and on to the control spindle F and wind 3 turns anti-clockwise round the control spindle.

Finally pass the cord through slot G on the drive drum and tie together the two

ends of the cord, making sure that the arm E is under tension. With the tuning gang fully closed, attach the cursor H and align it with the "L" of "Light" on the f.m. tuning scale.

Switches.—S1-S20 are waveband switches which are located in a rotary unit in the top left-hand corner of the chassis. On the circuit diagram each switch is given a code letter to show its closed position according to the switch key. S21 is the battery on/off switch which is ganged with the volume control.

Batteries.—Four 1.5V cells, U11 or V11.

Drive Mechanism Sticking.—If difficulty is experienced with the drive mechanism sticking, the drive drum spindle should be lubricated with light machine oil and the gear assembly should be lightly greased.

Blocking on M.W. or L.W.—Intermittent blocking on m.w. or l.w., which may also occur when the receiver is subject to impulsive interference (e.g. switching on lights), can be due to excessive gain in the final i.f. stage. To overcome this trouble, a 56kΩ resistor should be fitted across the primary of the i.f. transformer L16.

C20 and R13.—Instances have been found where C20 and R13, which are wired on the foil side of the printed panel, are short-circuited by the copper foil. In these instances a break should be made in the copper foil between the two points where C20 and R13 are connected.

Plan of the r.f. printed panel illustrating the alignment adjustments only. L24 and L29 are adjusted by expanding or contracting the turns as required
