1-2. DETAILED CIRCUIT ANALYSIS

The following describes the function or operation of all stages and controls. The text sequence follows signal paths. Stages are listed by transistor reference designation at the left margin; major components are also listed in a similar manner. Refer to the block diagram on page 11 to 12 and the schematic diagram on page 47 to 50.

Stage/Control

Function

Fm Front End

Balun B901

This transformer matches 300ohm twin lead to the fm front-end's input stage and thereby couples the receiver signal to the front-end.

Passive rf circuit

A triple-tuned circuit is employed between the antenna and mixer transistor. This passive coupling circuit contains no active amplifiers, so it is perfectly linear and cannot produce distortion and overload components. Thus, the factors that contribute to spurious responses are eliminated ahead of the mixer.

Local oscillator O102 Supplies heterodyning voltage to the mixer via L104. The circuit is a modified Hartley type with feedback applied to the emitter from the tap on Stage/Control

Function

L104.

AFC circuit D101, D102 C120 An automatic frequency control circuit is incorporated in the oscillator circuit to eliminate frequency drift and precise tuning difficulty. The principle of afc operation is as follows:

afc operation is as follows: When the tuner is correctly tuned, the intermediate frequency is 10.7 MHz and no dc correction voltage is produced by the ratio detector as shown in the "S" curve response of Fig. 1-1. Thus the voltage applied to diode D101 is determined solely by the positive fixed reverse bias voltage supplied by zener diode D102. Now assume that the local oscillator frequency changes by $+\Delta f$. This means that the new intermediate frequency is 10.7 $+\Delta f$. See Fig. 1-1. As the result a positive dc component is fed back to the anode of D101, decreasing the reverse voltage to it, and making D101's barrier capacitance increase. This decreases the local oscillator's frequency, since the series circuit composed of C120 and D101 is connected in parallel with the tank circuit of the local oscillator. Conversely, if the local oscillator frequency decreases a negative dc voltage is fed back to D101 increasing the local oscillator frequency.

Mixer Q101

C120

RF signals and local oscillator voltage are heterodyned in the gate-source junction of mixer Q101 to produce 10.7 MHz i-f output signal.

IFT101

Transformer IFT101 and capacitor C106 and C107 form a 10.7 MHz "high-C" tuned circuit. This type of circuit has the advantage of reducing the higher order harmonics of 10.7 MHz which cause crossmodulation or spurious interference.

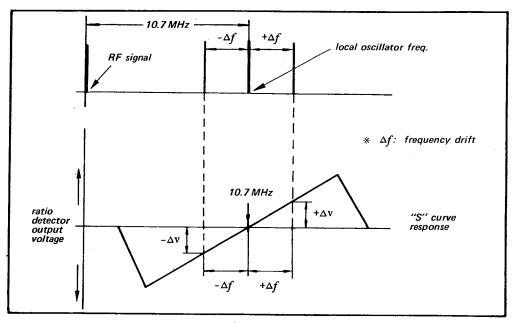

Fig. 1-1. Local oscillator's frequency drift and afc voltage relationship

Stage/0	Control
---------	---------

Function

Function

I-f preamplifier Q103

The i-f signal coupled to the base of i-f preamplifier Q103 by the secondary winding of IFT101 is amplified to achieve a favorable signal-to-noise ratio before application to the filters in the i-f strip.

I-f Amplifier

I-f amplifiers Q201 to Q205 CF201 to CF206

These i-f stages are basically RC coupled amplifiers (except Q205) that provide essentially flat response. The selectivity of this section is determined by three pairs of filters CF201, CF202, CF203, CF204, CF205 and CF206 in the interstage coupling path. Each of these filters is a two-section ceramic filter that operates in the "trapped-energy" mode. The filters provide extremely-sharp skirt selectivity and flat response inside the passband. Thus, these filters largely determine overall tuner selectivity.

I-f output Q206 Signal at the base of Q206 has had all amplitude variations removed by the preceding lim-

Stage/Control

iters, and only selected signals have been passed by ceramic filters. Q206 provides power to drive the ratio detector.

Diode limiters D201 to D206 D209, D210

Limiting is accomplished by diode pairs, connected in parallel and poled in opposite directions. The diodes conduct when the signal across them exceeds the barrier potential of about 0.6 volts in the forward direction. Thus the signal is limited in both directions to 1.2 volts peak-to-peak. The diodes provide symmetrical limiting.

Ratio detector D207, D208 T201 and diodes D207 and D208 form a balanced ratio detector that transforms the frequency-modulated signal into an audio signal. Output appears across C216.

Muting circuit Q207, Q208, Q209, Q210 D211 to D213 The i-f signal is extracted from limiter diodes D203 and D204 to drive the muting circuit. The extracted i-f signal is amplified by Q208 (FET) enough to drive voltage doubler D212 and D211 through tuned transformer T202.

Function

D213 provides positive fixed bias for Q209 through D212 and D211. T202 determines the bandwidth necessary to control the muting circuit without generating interstation or detuning noise. The output of the voltage doubler is a positive dc voltage proportional to the carrier levels of weak rf signals. Q209 and Q210 form a switching circuit which is driven by the voltage doubler. Q209 is normally cut off, thus forcing

The collector of Q210 is connected to the gate of FET Q207 through MUTING switch S7. FET Q207 acts as an electronic switch which is inserted between the ratio detector and MPX decoder, and is controlled by the gate voltage applied.

Q210 into conduction.

With the MUTING switch ON, fm signals of average strength keep Q209 saturated, thus cutting off Q210. This causes Q207 to conduct and maintain normal operation.

Weak stations and interstation noise can not produce sufficient dc voltage at the base of Q209 to keep it conducting. As a result, Q209 cuts off.

This saturates Q210 and cuts off Q207, accordingly, the audio output is muted. With the MUTING switch OFF, Q207 is kept conducting regardless of the strength of the fm signal by a positive bias voltage on its gate. RV201 adjusts the muting level.

Stereo-mono automaticswitching circuit Q210, D409 The collector of Q210 is also connected to the output terminal of the MPX decoder's frequency doubler through diode D409.

This prevents noisy stereo reception by automatically switching the MPX decoder's operation into the monaural mode. This is needed because in fm stereo

Stage/Control

Function

broadcasting, the S/N ratio of a demodulated stereo signal degrades much more rapidly than that of a mono signal when the input signal strength decreases. As Q210 is forced into conduction by weak stations, the frequency doubler's output is effectively grounded, stopping the operation of the stereo demodulator. Thus, automatic switching of stereo to mono according to the input rf signal level is achieved.

TUNING meter M901

Center-zero meter assures correct tuning by utilizing the ratio detector's characteristic.

As indicated in Fig. 1-1 no dc

voltage is produced across connection of R243 and R244 and ground when the tuner is correctly tuned. Deflection on the meter indicates the amount of

deviation from the carrier frequency received.

Note that the meter will indicate zero-reading when the tuner is not receiving any off-the-air signal.

SCA trap L203, C220 The composite signal containing monaural information from 0 to 15 kHz, the 19 kHz pilot carrier, and the fm stereo signal at 38 kHz is fed to Q207 through trap L203-C220. This trap removes the unwanted SCA signal to the base of Q401 (the 19 kHz amplifier) through Q207.

MPX Decoder

19 kHz amplifier Q401

This stage serves two functions. It extracts the 19 kHz pilot signal by means of a tuned circuit at its drain, and provides a low-impedance source of composite stereo signal (without pilot carrier) at its source. By using an FET, harmonics of the 19 kHz and 38 kHz components are reduced to a low level thereby causing less carrier leak or beat interferance.

Function

Frequency doubler Signals developed at the drain D401, D402

of Q401 are transformer coupled to a fullwave rectifier consisting of D401 and D402. The output of this rectifier is not filtered, resulting in two positive pulses for each input cycle. Thus, the 19 kHz pilotcarrier frequency is effectively doubled by D401 and D402. However, the wave form is not sinusoidal at the base of Q402.

38 kHz amplifier Q402

The 38 kHz pulses produced by D401 and D402 are amplified by Q402. The tank circuit at the collector of Q402 is tuned to 38 kHz to restore these pulses to a sinusoidal waveform. This signal is transformer coupled to the bridge-type demodulator to supply sampling drive for the demodulator.

STEREO lamp circuit Q403

The STEREO indicator lights when the FUNCTION switch is set to the FM-AUTO STEREO position and an fm stereo signal is received. The emitter of Q402 is connected to the base of Q403 (which is normally cut off).

The circuit operates as follows: When a composite stereo signal is applied to the multiplex decoder, the 38 kHz pulses produced at the output of the frequency doubler yield a higher average current flow through Q402. This forces Q403 into conduction, lighting STEREO indicator lamp PL904.

Multiplex demodulator D405, D406, D407, D408

The demodulator circuit employs four diodes in a balancedbridge arrangement. This system has the advantage of cancelling residual rf components (38 kHz signal, some 19 kHz signal, and higher-order harmonics of these frequencies.)

"L" and "R" components are developed at each side of the bridge as the result of demodulation, when the receiver is Stage/Control

Function

operated in the stereo mode. In the monaural mode, diodes D405 and D408 are forward biased by supply voltage through R405, the stereo indicator lamp, R412, R414, and R413, so these diodes merely act as small resistances. Under this condition, the monaural signal is applied to both "L" and "R" audio amplifiers.

De-emphasis capacitors C902, C903 C422, C423 These capacitors provide the roll off at high audio frequencies necessary to compensate for preemphasis at the transmitter. S10 should be set to the proper time constant. Specified deemphasis time constant is 75 micro-seconds in USA and CAN-ADA, 50 micro-seconds in Europe.

Q404, Q405 Q406, Q407

Audio preamplifier Demodulated L and R signals are amplified by these stages to the level required at the input of the following low pass filter.

RV401

Separation control The network that connects the emitters of Q404 and Q405 provides a form of negative feedback between left and right channels. Any residual "L" signal in the "R" channel (which is about 180° out of phase) is cancelled out by the "L" signal from the "L" channel.

> The same is true of residual "R" signal in the "L" channel. RV401 is therefore set for maximum separation.

LPF401

Filters out the unwanted higherorder harmonics of 19 kHz and 38 kHz leakage to obtain clear audio.

A-m Tuner

Local oscillator Q305

This stage supplies injection voltage to the mixer via L904. In this oscillator circuit feedback is applied to the emitter of Q305 from low-impedance winding on oscillator coil L304.

Stage/Control	Function	Stage/Control	Function

The level of the signal applied

fed back to the gate of Q302

Function

to the following tone-control amplifier is determined by the setting of RV601.

LOUDNESS switch This switch and R601, R602, S5 C601 C602 compensate for the

C601, C602 compensate for the characteristics of the human ear which vary according to the loudness of the sound being heard. When this switch is set to ON and the VOLUME control is set for 30 dB attenuation, the overall frequency response is increased 10 dB at 50 Hz and 4 dB at 10 kHz with reference to the level at 1 kHz.

Tone-control amplifier Q601, Q602 (Q651, Q652) This direct-coupled two-stage amplifier has basically flat response, but it operates as a negative-feedback type tone-control circuit. The output generated at the collector circuit of Q602 is fed back to the emitter circuit of Q601 through the treble and bass tone-control network.

TREBLE control RV603 (RV653)

Increases or decreases the amount of negative feedback voltage determined by the setting of RV603. It has a range of 10 dB at 10 kHz.

BASS control RV604 (RV654) Similar to the treble control except for filter components and frequency characteristics, however in this circuit the negative feedback voltage is determined by the setting of RV604. This has a range of 10 dB at 100 Hz.

HIGH FILTER S6

The high-cutoff filter (R616 and C613) eliminates unwanted high-frequency components (5 kHz and higher) from the input signal when this switch is ON.

Power Amplifier Section

Preamplifier Q701, Q702

Q701 and Q702 form a paraphase amplifier but signal out-

Stage/Control

Function

put is extracted from the collector circuit of Q701. This circuit has a various advantages in direct coupling system. One is high stability despite temperature variations and another is high input impedance without reducing the amplifier's gain. The ac output appears across load resistor R707 (R757) in the collector circuit. An emitter decoupling dircuit is formed by the emitter-base resistance of Q702, C702 and R710 in the base circuit of Q702.

This circuit forms a frequency-selective ac bypass circuit to reduce the amplifier's gain at very low frequencies. Common emitter-resistor R709 keeps the dc current flow constant in the Q701 and Q702, thus increasing dc stability.

Bias power supply D701, D702

These diodes are forward biased by positive and negative power supply voltage through RV701 and RV751. They provide a stabilized voltage to bias transistor Q701 that is used to make the output terminal balance at zero dc through RV701.

Ac balance adj. RV701 (RV751)

Thermal compensation and noise suppressor D703

As all the stages are directly coupled, dc stability is required. The negative temperature co efficient of D703 provides thermal compensation for the following driver stage.

It also acts as a noise suppressor to reduce the popping noise due to unbalanced current flow in the following stages when the power switch in turned off.

Driver Q703

Though this stage is a conventional flat amplifier, it determines the output voltage swings because the following stages are basically in the emitter-follower configuration. The ac load resistor for this stage is R716.

Function

Dc bias adj. (idling current) Q704, RV702 Q704 is forced to conduct and operates as a small resistance providing the necessary forward bias on the two cascaded emitter-followers.

RV702 controls the base bias of Q704, determining the impedance between the emitter and collector of Q704, and thereby controls the dc bias voltage for the following complementary circuit.

Thermal compensator for dc bias D901 The negative temperature coefficient of D901 provides thermal compensation for the complementary and power transistor circuits.

D901 is attached to the power transistor's heat sink to detect temperature increases in the power transistors.

Complementary circuit Q708, Q709

These transistors operate as emitter-followers to provide the current swings demanded of the output stages and also provide the necessary phase inversion. Phase inversion is performed by using PNP and NPN type transistors.

Power transistor Q901, Q902

The output transistors (Q901 and Q902) are connected directly to a power supply of about ±50 V. Q902 supplies power to the load during the positive half cycle and Q901 operates during the negative half cycle. As all the stages are directly coupled and designed to obtain zero potential at the output terminal, the large coupling capacitor at the output (which may cause power loss or distortion at low frequencies) is eliminated.

Protection circuit

To protect overloaded power transistors from destruction, a new protection circuit is employed. In the event of a short circuit at the output terminals, the protection circuit holds the current in the power transistor low enough not to make it Stage/Control

Function

overheat and also limit the input drive signals.

Fig. 1-2 shows a partial schematic diagram detailing the protection circuit. With reference to this diagram, the protection circuit operates as follows:

Since the protection circuit is identical for positive going half cycles and negative going half cycles, only the positive going half cycle operation is described here. Q705 limits the positivegoing half cycle of the drive voltage applied to the base of Q708 when power consumption at the Q902 collector exceeds the safety margin. Since power dissipation at the collector can be considered a function of collector voltage and current, the trigger signal for O705 is taken from the collector and emitter. Base voltage is partly determined by the ratio of resistance of R722 and series resistance of R729, R738 and RL (load). Base voltage is also determined by the current flow in the R738 and the collector voltage of Q902. During normal operation, Q705 is cut off.

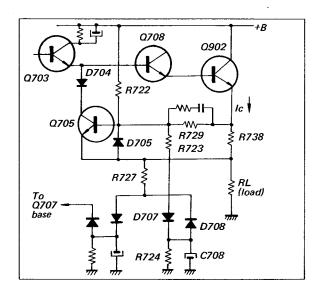

Fig. 1-2. Simplified protection circuit

When excessive current flows in the power transistor or power dissipation at the collector of power transistor exceeds the specified value, Q705 turns on and limits the input drive voltage to the power transistor. Limiting operation is also actuated by the condition of the load. The base voltage of Q705 is determined by the resistances R738, R729, R723, R724 and RL (load). D707 is employed to stop reverse voltage from applied being during the negative going-half cycle. Q705 turns on limiting the input drive voltage to the power transistor when the load resistance decreases to Under reactive some extent. load conditions in class B amplifiers maximum current will flow when the voltage across the power transistor is maximum and this is the worst case for secondary breakdown. Fig. 1-3. As all speakers have reactive properties, a protection circuit which covers the reactive region is required.

Fig. 1-3 shows the operating load lines for one half of a class B output stage under con-

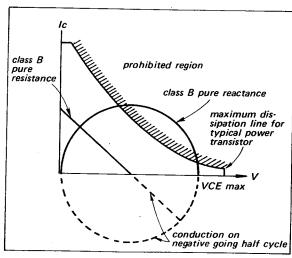

Fig. 1-3. Resistive and reactive load lines for class B output stage showing breakdown risk in purely resistive load

Stage/Control

Function

ditions of equal load impedance; in one case the load is purely resistive and in the other case purely reactive. It is apparent that the reactive load case could result in transistor failure. D708, C708 and R727 form a charging circuit charging the base voltage according to the reactive voltage induced in the load to obtain proper protection operation. C708 and R724 form a discharging circuit to detect reactive dc voltage. D705 protects Q705 from breakdown between base and emitter due to detected reactive voltage D704 protects across C708. Q705 from the breakdown between collector and emitter during the negative-going half cycle.

Q706

Q706 is inserted in the collector circuit of Q707 to increase protection sensitivity of negative going half-cycle.

Power supply rectifier D801

A full-wave bridge rectifier provides a positive and a negative dc power supply for the power amplifier.

Rectifier D802, D803

A half-wave rectifier D802 (D803) and ripple filter (C808, R801) supply well-filtered dc power to the complementary stage.

Ripple filter Q801 R804, R806 C810 Q802 R803, R805 C809 These components reduce the ripple voltage in the dc power supply for the pre-driver and driver stages of the power amplifier section to an extremely-low value. Q801 and Q802 serve as an electronic filter to supply well filtered dc of about ±54V to each stage.

Muting circuit for toneamplifier and ripple filter Q803, Q804, Q805 R813, C814

This muting circuit prevents a loud "pop" (due to initial current flow to the tone amplifier) that might damage a delicate high-fidelity speaker system.

R813 and C814 comprise an

RC network with a long time

Function

constant. This eliminates poping because Q805 (ripple filter) is brought into conduction gradually.

The base of O805 is connected to the collector circuit of Q804 through R817, while the base of Q804 is directly coupled to the collector of Q803. At the instant of turning on the power switch S8, Q803 is off due to the long time constant of bias circuit, while Q804 is forward biased by R814 shorting the Q805's base to the ground. Thus, Q805 does not deliver power to the tone amplifier. As Q803 is gradually turned on due to its long time constant circuit Q804 is gradually cut off,

Stage/Control

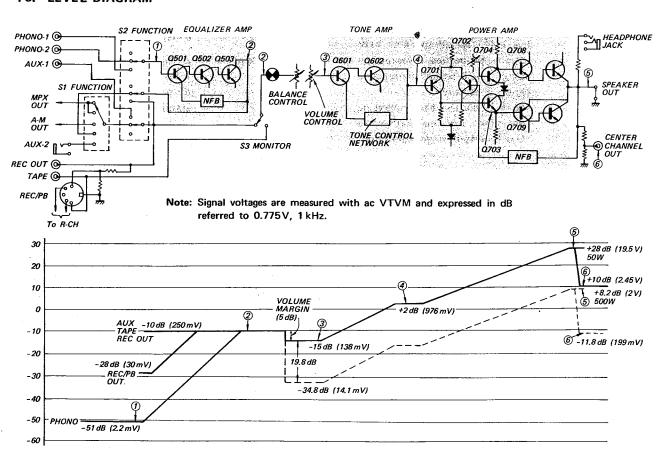

Function

turning on the Q805. As the result, Q805 is brought into conduction gradually.

Ripple filter Q805 R816, R817 C815, C816 Reduces the ripple voltages in the dc power supply for the tone amplifier stages to an extremely low value.

Power supply for tuner section D804 Q806 D805, D806 Dc output from the rectifier D804 is filtered by C819 and applied to series regulator Q806. Since the voltage at the base of Q806 is kept constant by means of zener diodes D805 and D806, the emitter voltage remains constant regardless of load or linevoltage variations. The regulated and well filtered output of 15 V is supplied to the tuner section.

Function

Stage/Control

Function

Speaker protection circuit

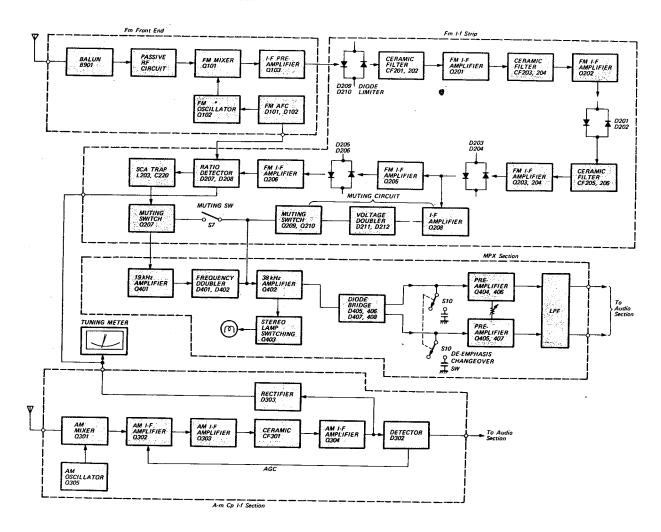

In a direct-coupled power amplifier, some faults in the prior transistor appears as a large unbalanced dc voltage across output terminal. This might damage a delicate speaker system. Therefore, the STR-6065 incorporates speaker protection circuit which operates as follows (refer to Fig. 1-4):

The output signal is extracted from the output terminal through a low-pass filter (R822 or R823, C823 and C824) and fed to the bridge rectifier (D807 \sim D810). Because of

this filter, the voltage applied to the bridge rectifier is only the very-low frequency or dc component caused by transistor faults. When the rectified dc voltage becomes large enough, it starts the Hartley oscillator (Q807 and T801).

The oscillator's output is rectified by D811 and thus provides trigger voltage for SCR D813. When the trigger voltage is applied to the gate of SCR, the SCR turns on and shorts the base voltage of Q708 to ground through R720, D814, the SCR,

1-4. BLOCK DIAGRAM - Tuner Section -

Function

and D815. The base voltage of Q709 is also shorted to ground through R719, D812, the SCR, and D816, stopping any current flow in the output stage and thus protecting the speaker system. Note that the direction of diodes D812, SCR D813 and D814 which also ensure the speaker protection operation even if one of the power transistors is damaged by accident, forcing the other power transistor into secondary break down.

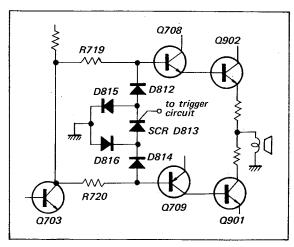

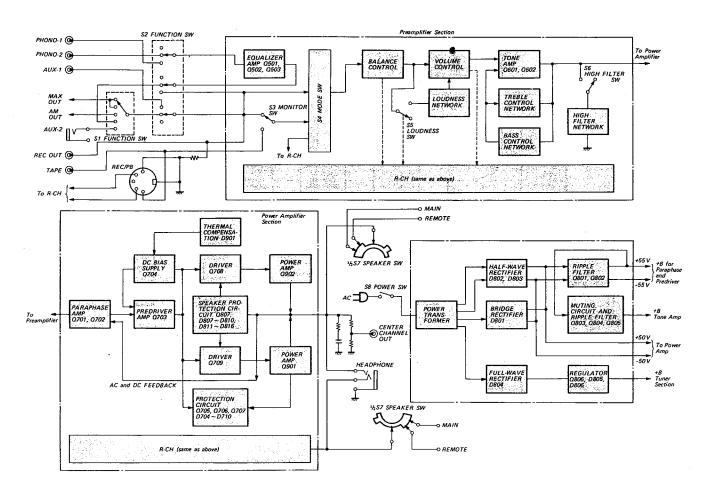

Fig. 1-4 Speaker protection circuit

1-5. BLOCK DIAGRAM - Audio Section -

SECTION 2 DISASSEMBLY AND REPLACEMENT PROCEDURES

WARNING

Unplug the ac power cord before starting any disassembly or replacement procedures.

2-1. TOOLS REQUIRED

The following tools are required to perform disassembly and replacement procedures on the STR-6065.

- 1. Screwdriver, Phillips-head
- 2. Screwdriver, ½" blade (3 mm)
- 3. Pliers, long-nose
- 4. Diagonal cutters
- 5. Wrench, adjustable
- 6. Tweezers
- 7. Electric drill
- 8. Drill bits
- 9. Prick punch
- 10. Hammer, ball-peen
- 11. Soldering iron, $40 \sim 150$ watts
- 12. Solder, rosin core
- 13. Cement solvent
- 14. Cement, contact
- 15. Thermal compound or silicone grease

2-2. HARDWARE IDENTIFICATION GUIDE

The following chart will help you to decipher the hardware codes given in this service manual.

Note: All screws in the STR-6065 are manufactured to the specifications of the International Organization for Standardization (ISO). This means that the new and old screws are not interchangeable because ISO screws have a different number of threads per mm compared to the old ones. The ISO screws have an identification mark on their heads as shown in Fig. 2-1.

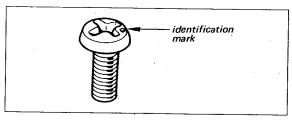

Fig. 2-1. ISO screw

— Hardware Nomenclature —

P - Pan Head Screw
PS - Pan Head Screw with Spring Washer
K - Flat Countersunk Head Screw 💠
B - Binding Head Screw
RK- Oval Countersunk Head Screw
T - Truss Head Screw
R - Round Head Screw
F - Flat Fillister Head Screw
SC - Set Screw
E - Retaining Ring (E Washer)
W — Washer SW — Spring Washer LW — Lock Washer N — Nut
Example —
Type of Slot
P 3x10 Length in mm (L) Diameter in mm (D) Type of Head

2-3. TOP COVER AND BOTTOM PLATE REMOVAL

- 1. Remove the two machine screws at each side of the receiver, and lift off the top cover.
- 2. Remove the ten self-tapping screws (\oplus B 3×6) at the bottom of the receiver as shown in Fig. 2-2. This frees the bottom plate.

2-4. FRONT PANEL REMOVAL

- 1. Remove the top cover as described in Procedure 2-3.
- 2. Pull all the knobs off.

3. Remove the two self-tapping screws (@B 3x6) and two hex-nuts securing the front panel to the front sub-chassis as shown in Fig. 2-3. Place a piece of cardboard or cloth between the wrench and front panel to avoid marring the panel as shown in Fig. 2-4. Now the front panel is free for servicing.

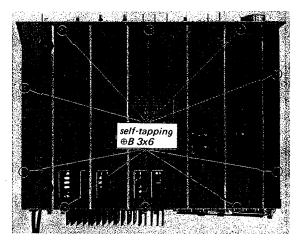

Fig. 2-2. Bottom plate removal

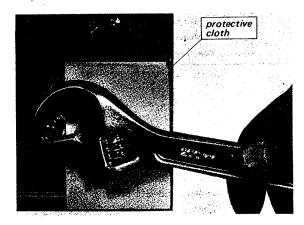

Fig. 2-4. Hex nut removal

2-5. DIAL-CORD RESTRINGING

Preparation

- Remove the top cover as described in Procedure 2-3.
- 2. Cut a 1,500 mm (59") length of dial cord.
- 3. Tie the end of the cord to a spring as shown in Fig. 2-5.
- 4. Rotate the tuning-capacitor drive drum fully clockwise (minimum capacitance position).

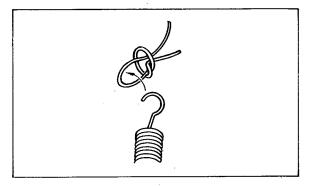

Fig. 2-5. Tying square knot to the coil spring

Procedure

While referring to Fig. 2-6, proceed as follows:

- Hook the spring to one hole of the drive drum as shown in Fig. 2-7.
- Run the cord through the slot in the rim of the drum and wrap a half clockwise turn in the inner groove.
- 3. Run the cord over pulley "A" and, then wrap two counterclockwise turns around the tuning shaft.

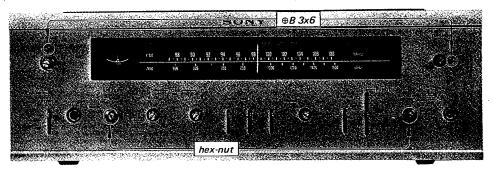

Fig. 2-3. Front panel removal

- 4. Run the cord over pulleys "B", "C" and "D", then wrap two clockwise turns around the drum from outer groove to inner groove as shown in Fig. 2-8.
- 5. Pass the doubled end of the cord through the eyelet, then hook it to the spring as shown in Fig. 2-9.

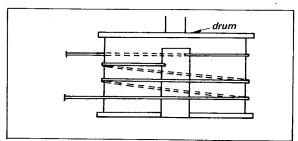

Fig. 2-8. Wrapping the dial cord

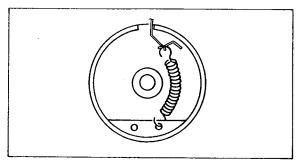

Fig. 2-7. Coil spring installation

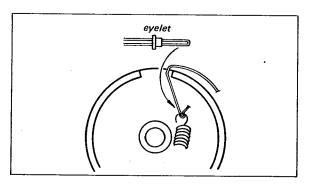

Fig. 2-9. Finishing dial cord stringing

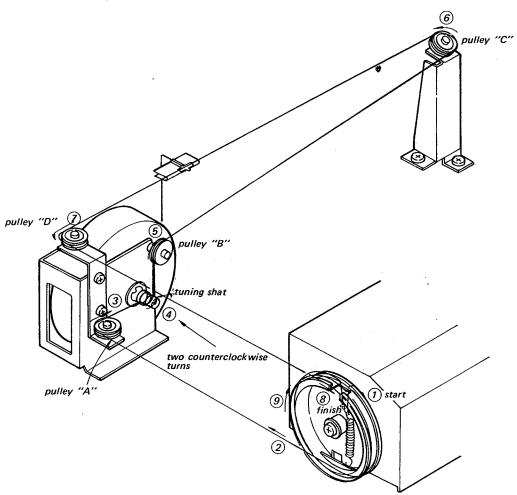

Fig. 2-6. Dial cord stringing

- 6. Tighten the cord, then squeeze the eyelet so that the spring is under tension. Make a knot in the cord end to keep it from slipping out of the eyelet.
- 7. After completing the dial-cord stringing, make sure that the tuning system works properly. Apply a drop of contact cement to the finish point.

2-6. MECHANICAL DIAL CALIBRATION

Note: This is required after replacing the dial cord, dial scale or front-end assembly.

- Put the dial pointer on the cord as shown in Fig. 2-10 and move it to a position where the pointer coincides with the left gap on the dial scale as shown in Fig. 2-11, when the tuning capacitor is set to the maximum capacitance.
- 2. Apply a drop of contact cement to the tab of the dial pointer.

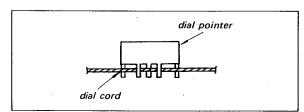

Fig. 2-10. Dial pointer installation

2-7. DIAL SCALE REPLACEMENT

Remove the top cover as described in Procedure 2-3.

- Remove the front panel as described in Procedure 2-4.
- Remove the two self-tapping screws (

 B 3x6) securing the dial-scale holder to the front subchassis as shown in Fig. 2-12.
- 4. Remove the defective dial scale and then install the replacement scale.

2-8. PILOT-LAMP REPLACEMENT

Prepare for replacement any of the pilot lamps by removing the top cover as described in Procedure 2-3.

Meter Lamp

- Straighten the tab of the meter-lamp holder to permit the removal of the meter-lamp socket.
- Pull out the meter-lamp socket, and then unscrew the lamp from the socket and install the new lamp.

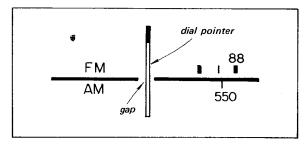

Fig. 2-11. Mechanical dial calibration

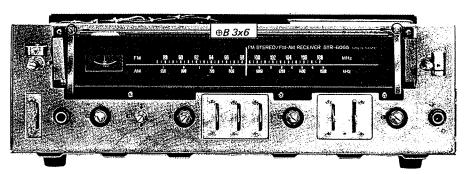

Fig. 2-12. Dial scale removal

Stereo Lamp

- 1. Pull the lamp and rubber grommet from its holder with tweezers as shown in Fig. 2-13.
- 2. Cut the lamp leads and solder the lead wires to the new lamp as shown in Fig. 2-14.
- Wrap the soldered connections with electrical tape.
- 4. Install the new lamp in its holder.

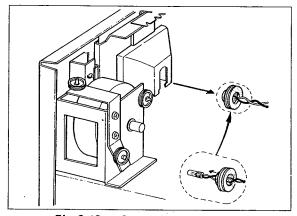

Fig. 2-13. Stereo lamp removal

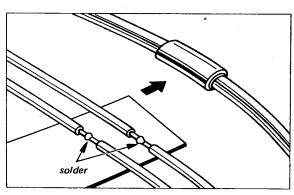

Fig. 2-14. Stereo lamp replacement

Dial Lamp

- 1. Remove the front panel as described in Procedure 2-4.
- 2. Pry out the fiber lamp shade, and then remove the lamp.

2-9. TUNING METER REPLACEMENT

- Remove the top cover as described in Procedure 2-3.
- 2. Unsolder the leads from the defective meter.

- Remove the two self-tapping screws (⊕B 3x6) securing the meter holder to the chassis as shown in Fig. 2-15.
- 4. Remove the meter, and install the new one.

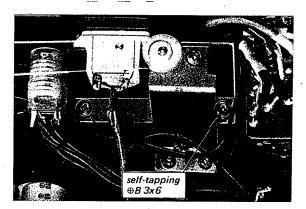

Fig. 2-15. Meter holder replacement

2-10. CONTROL AND SWITCH REPLACEMENT

Prepare for replacing any of the controls or switches by removing the wooden case as described in Procedures 2-3 and 2-4. Refer to Fig. 2-16.

TONE Controls

- 1. Apply a drop of cement solvent to the ring spacer on the TREBLE control. Wait a few seconds for the cement to dissolve, and pry out the spacer with a screw driver.
- 2. Remove the hex nuts that secure the BASS and TREBLE controls to the front-subchassis.
- 3. Carefully remove them along with the tonecontrol circuit board.
- 4. Cut each lug of the defective control on the board to remove the part.
- 5. Unsolder and remove the cipped lugs, and clean out the holes of the circuit board.
- 6. Install the replacement control.

POWER, HIGH FILTER, MUTING, MONITOR, FUNCTION (2), LOUDNESS Switches

- Remove the two screws (⊕PS 3x6) securing switches to the front subchassis as shown in Fig. 2-16.
- 2. Unsolder the lead wires from the defective switch, and then install the replacement switch.

SPEAKER, MODE, FUNCTION (1) Switches

- 1. Apply a drop of cement solvent to the ring spacer on the switches. Wait a few seconds for the cement to dissolve, and pry out the spacer with a screw driver.
- Remove the hex nuts that secure the switches to the front-subchassis as shown in Fig. 2-16.
- Unsolder the lead wires from the defective switch, and then install the replacement switch.

2-11. REAR PANEL REMOVAL

- Remove the top cover and bottom plate as described in Procedure 2-3.
- Unsolder the lead wire connecting between ground terminal and chassis.
- 3. Unsolder the coaxial cable from fm antenna terminal.
- Remove the six self-tapping screws ($\oplus B 3 \times 6$),

two of them secure the bar antenna holder to the chassis along with rear panel and others secure the rear panel to the chassis as shown in Fig. 2-17. This frees the rear panel.

2-12. REPLACEMENT OF COMPONENTS SECURED TO THE REAR PANEL BY RIVETS

- 1. Remove the rear panel as described in Procedure 2-11.
- Bore out the rivets using a drill bit slightly larger in diameter than the rivet. See Fig. 2-18.
- Punch out the remainder of the rivet with a nail set or prick punch.
- Remove the defective component, and install the new one.
- Secure the new component with a suitable screw and nut, or a repair rivet screw (Part No. 3-701-402).

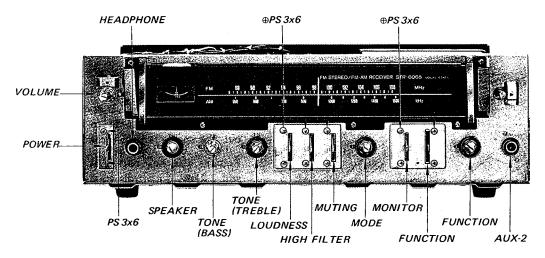

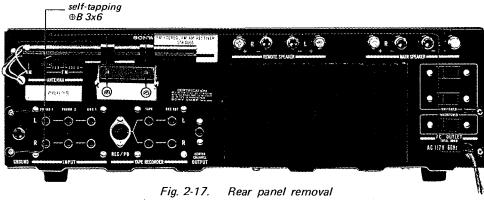

Fig. 2-16. Control and switch replacement

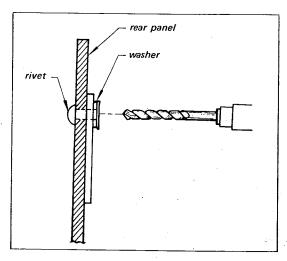

Fig. 2-18. Rivet replacement

2-13. POWER TRANSISTOR REPLACEMENT

- 1. Remove the top cover and bottom plate as described in Procedure 2-3.
- Remove the eight self-tapping screws (#B 3x8), (#P 3x8) securing the heat sink to the chassis as shown in Fig. 2-19, and then remove the four self-tapping screws (#B 3x8) securing the heat sink support to the top of the heat sinks.
- 3. Cut the emitter and base leads of the defective power transistor with a diagonal cutter. This prevents damage to the mica washer when remove the defective power transistor.

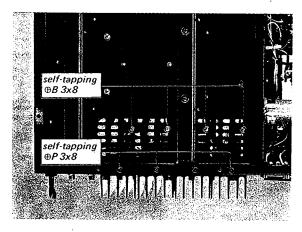

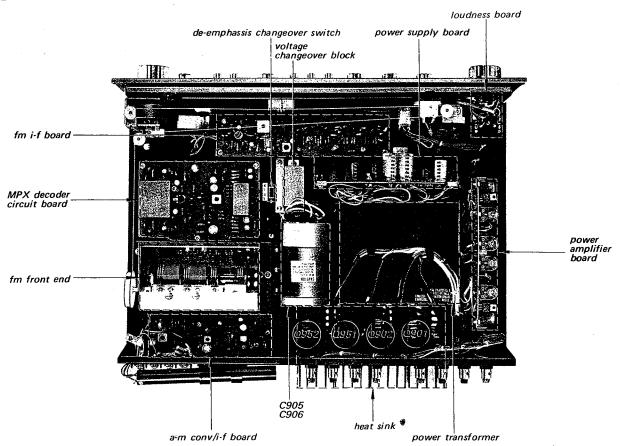

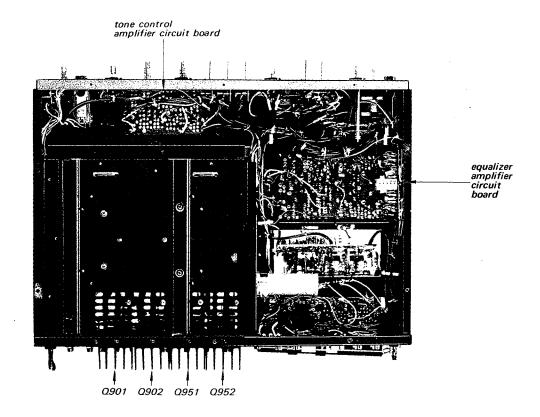

Fig. 2-19. Heat sink removal

- 4. Carefully draw back the heat sink, and then remove the two screws ($\oplus B 3 \times 14$) and nuts securing the power transistor to the heat sink.
- 5. When replacing the power transistor, apply a coating of a thermal compound or a heattransferring grease to both sides of the insulating mica washer. Any excess compound or grease squeezed out when the mounting bolts are tightened should be wiped off with a clean cloth. This prevents accumulation of conductive dust particles that might eventually cause a short.

2-14. CHASSIS LAYOUT

SECTION 3 ALIGNMENT AND ADJUSTMENT PROCEDURES

3-1. FM I-F STRIP ALIGNMENT

CAUTION

The ceramic filters in the fm i-f circuit are selected according to their specified center frequencies and color coded as shown in Fig. 3-1 and listed in Table 3-1. Check the color code of the filters to to identify the same center frequency when replacing any of these filters.

TABLE 3-1.

FM I-F CERAMIC FILTERS

Part No.	Color	Specified Center Freq.
1-403-562-11	red	10.70 MHz
1-403-562-21	black	10.66 MHz
1-403-562-31	white	10.74 MHz
1-403-562-41	green	10.62 MHz
1-403-562-51	yellow	10.78 MHz

Test Equipment Required

- 1. Standard fm signal generator
- 2. Ac VTVM
- 3. Oscilloscope
- 4. Alignment tools

Note: This alignment is needed only after IFT101 in the front end or T201 (discriminator transformer) has been replaced.

Preparation

- 1. Remove the top cover as described in Procedure 2-3.
- 2. Remove the front-end cover by loosening the two screws securing it to the chassis.
- 3. Connect the input cable of the ac VTVM to the REC OUT terminal (J105).

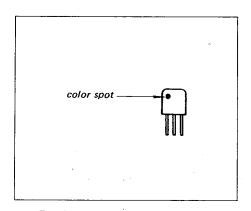

Fig. 3-1. Fm i-f ceramic filter

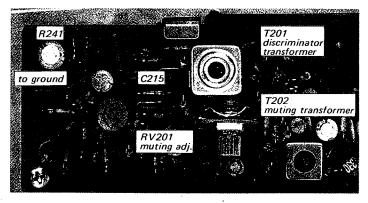

Fig. 3-2. Interruption of afc circuit and parts location

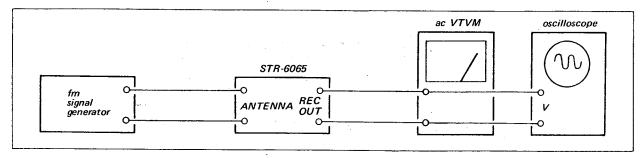

Fig. 3-3. Fm i-f, muting and front end alignment test setup

- 4. Connect the signal-generator's output to the fm antenna terminal.
- 5. Short the connection point of R242 and C215 (AFC circuit) to ground as shown in Fig. 3-2.

Procedure

 With the equipment connected as shown in Fig. 3-3, set the signal-generator's controls as follows:

Carrier frequency	98 MHz
Modulation	Fm, 400 Hz, 100%
Output level	30 µV (30 dB)

3. Turn the core of transformer IFT101 or T201 (bottom core) (See Fig. 3-2 or Fig. 3-4) with the alignment tool to obtain maximum output.

3-2. FM DISCRIMINATOR ALIGNMENT

Note: Before starting this alignment, the fm i-f alignment should be performed. There are two or three methods of discriminator alignment, but only the simplified method using the tuner's TUNING meter is described here.

Test Equipment Required

- 1. Oscilloscope
- 2. Alignment tools

Preparation

- Remove the top cover as described in Procedure 2-3.
- Connect the input cable of the oscilloscope to REC OUT (J105) terminal.
- 3. Short the connection point of R242 and C215 (AFC circuit) to ground as shown in Fig. 3-2.

Procedure

- With the equipment connected as shown in Fig. 3-5, set the receiver's control as follows: FUNCTION switch FM MONO MODE switch STEREO No signal should be received.
- Adjust the controls of the oscilloscope to provide a visible indication of noise. Always watch the oscilloscope to confirm that the tuner is not receiving any off-the-air signals.
- 3. Turn the top core (secondary side) of discriminator transformer T201 (see Fig. 3-2) with a hex-head alignment tool to obtain a null-point reading on the tuning meter. If the discriminator transformer (T201) is not aligned correctly, some deviation on the tuning meter will be observed.

Note: Turn the core carefully and slowly.

At both extreme positions of the top core, a null point will be observed.

The real null point should be obtained in the middle of the core's thread length.

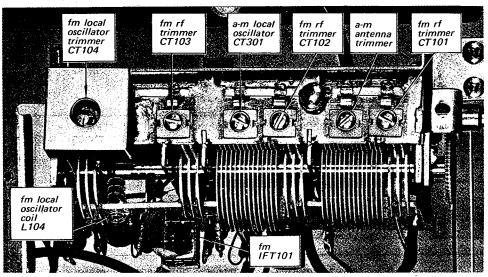

Fig. 3-4. Parts location

4. Repeat the above mentioned steps and fm i-f strip alignment two or three times.

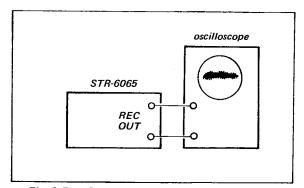

Fig. 3-5. Discriminator alignment test setup

3-3. MUTING ADJUSTMENT

Note: Two methods of muting alignment are available, signal generator alignment and alignment by using an off-the-air signal. You can use either of them.

Signal Generator Alignment

Test Equipment Required

- 1. Fm standard signal generator
- 2. Ac VTVM or oscilloscope
- 3. Alignment tool

Preparation

- Remove the top cover as described in Procedure 2-3.
- Turn the knob of RV201 (see Fig. 3-2) fully clockwise on the fm i-f and discriminator board.
- 3. Short the connection point of R242 and C215 (AFC circuit) to ground as shown in Fig. 3-2.

Procedure

1. With the equipment connected as shown in Fig. 3-3, set the receiver's controls as follows:

FUNCTION switch	FM MONO
MODE switch	STEREO
MUTING switch	ON

Follow the procedure given in Table 3-2.
 Note that the muting circuit should begin to operate at the symmetrical deflection point of TUNING meter when detuning the tuner to higher or lower than the reference carrier frequency.

Off-the-Air Signal Alignment

Accurate muting circuit adjustment can also be performed by utilizing off-the-air local fm signals instead of the fm S.S.G.

Note that a weak signal is best for this purpose.

3-4. FM FREQUENCY COVERAGE ALIGNMENT

CAUTION

Never attempt alignment of the frontend section except for the frequencycoverage and dial-calibraion adjustments. The front-end section of the tuner has been carefully adjusted at the factory, so very little adjustment is necessary in the field. Alignment need not be performed when the front-end FET is replaced since changes in FET parameters have little effect upon tuning. If an rf-stage adjustment is required, ask your nearest SONY Service Station to send your unit to the Factory Service Center for a complete front-end alignment. Exercise caution when returning the faulty unit so that it is not damaged in The warranty will not cover damage incurrent in transit to the Factory Service Center.

Note: Before starting this alignment, the discriminator-transformer alignment should be performed.

TABLE 3-2. MUTING ADJUSTMENT

Coupling Between Front End and SSG	SSG Frequency and Output Level	Tuner Dial Indication	Adjust	Remarks
Direct coupling	98 MHz 400 Hz. 30% Mod.	98 MHz	T202 See Fig. 3-2	Turn the core of T202 to obtain proper muting operation.

TABLE 3-3. FM FREQUENCY COVERAGE ADJUSTMENT

Step	Coupling Between Front End and SSG	SSG Frequency and Output Level	Tuner Dial Indication	Scope Connection	Adjust	Indication
1.	Direct coupling	87.5 MHz 400 Hz 100% Mod. 30µV (30 dB)	87.5 MHz	REC OUT (J105)	OSC coil L104 See Fig. 3-4	Maximum VTVM reading
2.	Same as above	108 MHz 400 Hz 100% Mod. 30µV (30 dB)	108 MHz	Same as above	OSC trimmer CT104 See Fig. 3-4	Same as above

Signal Generator Alignment

Test Equipment Required

- 1. Standard fm signal generator
- 2. Ac VTVM
- 3. Alignment tools

Preparation

- Remove the top cover as described in Procedure 2-3.
- 2. Connect the equipment as shown in Fig. 3-3.
- 3. Set the receivers controls as follows:

 FUNCTION switch FM MONO

 MODE switch STEREO
- 4. Short the connection point of R242 and C215 (AFC circuit) to ground as shown in Fig. 3-2.

Generator Alignment

Follow the procedures given in Table 3-3 when performing this alignment with an fm signal generator. Be sure that the dial is mechanically calibrated as described in Procedure 2-6.

Off-the-Air Alignment

Accurate dial calibration and a frequency-coverage test can also be performed by utilizing off-the-air local fm signals. However, before performing the following procedure, be sure that the dial pointer is correctly positioned, as described in Procedure 2-6.

Procedure

- Short the connection point of R242 and C215 (AFC circuit) to ground as shown in Fig. 3-2.
- Tune the receiver to the lowest-frequency station.

- 3. Check the dial scale for a calibration accuracy of ±200 kHz from the carrier frequency of the station. If the dial-accuracy deviation exceeds this limit, turn the local-oscillator coil L104 slightly as shown in Fig. 3-4 until optimum dial calibration is obtained.
- 4. Tune the receiver to the highest-frequency station in your locality. If the dial-calibration error is excessive, adjust local-oscillator trimmer CT104 (see Fig. 3-4) to obtain maximum calibration accuracy.
- 5. Repeat Steps 3 and 4.

3-5. FM STEREO SEPARATION ADJUSTMENT

Test Equipment Required

- MPX generator
- 2. Fm signal generator
- 3. Audio oscillator
- 4. Ac VTVM
- 5. Oscilloscope
- 6. Alignment tools

Preparation

Before starting the stereo-separation adjustment, check and adjust the phase between the 19-kHz pilot signal and the sub-channel signal in the MPX stereo generator as follows:

(1) With the equipment connected as shown in Fig. 3-6, set the MPX and audio signal-generator's control as follows:

MAIN CHANNEL	OFF
SUB CHANNEL	ON
PILOT (19 kHz)	OFF

AUDIO O	SCILLATOR	
OUTPUT	***************************************	400 Hz,
		250 mV

- (2) Adjust the oscilloscope controls to obtain a visible indication. Be sure the scope's horizontal display switch is set for external input.
- (3) Turn the pilot-signal (19 kHz) phase control to obtain an in-phase and stable lissajous pattern as shown in Fig. 3-7.

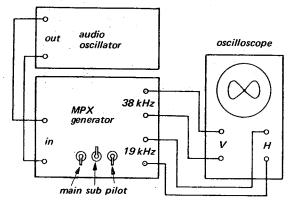

Fig. 3-6. MPX generator preadjustment

Fig. 3-7. Lissajous pattern

Procedure

The above mentioned modulation levels can be set as follows:

- (a) With the equipment connected as shown in Fig. 3-8 set the MPX stereo generator controls as follows.

 MAIN CHANNEL OFF
 SUB CHANNEL OFF
 19 kHz (PILOT) ON
- (b) Adjust the 19-kHz signal level to obtain a 7.5-kHz deviation on the FM SSG modulation indicator.

(c) Reset the MPX stereo-generator's control

- as follows:

 MAIN CHANNEL ON

 SUB CHANNEL OFF

 19 kHz (PILOT) OFF

 INPUT SELECTOR L-CH
- (d) Adjust the audio-oscillator output (400 Hz) to obtain a 33.75-kHz deviation on the FM SSG modulation indicator.
- (e) Set all controls to ON.

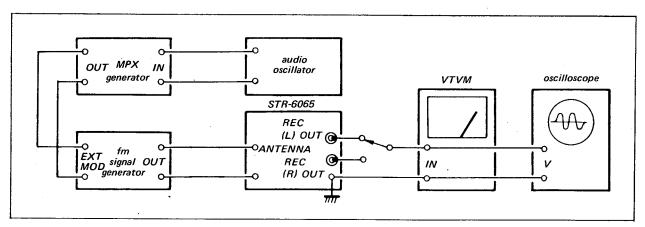

Fig. 3-8. Fm stereo separation adjustment test setup

- 2. Precisely tune the set to the S.S.G's carrier frequency then turn the top core of switching transformer T401 (see Fig. 3-9) to obtain maximum output at the left channel. Note that this adjustment is closely related to stereo distortion.
- 3. Record the output level of the left channel when the MPX generator input selector is set to the left channel.
- 4. Switch the input selector to the right channel and read the residual signal level in the left channel.
- 5. The output-level to residual-level ratio represents the separation. Adjust separation adj. control RV401 (see Fig. 3-9) for minimum residual level. Check the right channel for separation. Usually, about an 8 to 9 dB difference in channel separation exists. Readjust RV401 for minimum difference between

left-and right-channel separation. While doing this, remember that the output level also changes according to the setting of RV401.

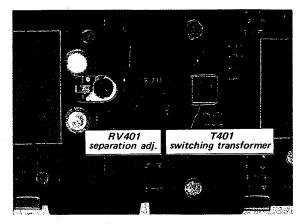

Fig. 3-9. Parts location

MEMO	
·	
·	· · · · · · · · · · · · · · · · · · ·

3-6. A-M I-F STRIP ALIGNMENT

Preparation

Remove the top cover as described in Procedure 2-3. Then set the receiver's FUNCTION selector to AM.

Note: To perform this alignment, the local oscillator should be killed. To do this, shunt the local oscillator capacitor with a 0.02-µF capacitor as shown in Fig. 3-10.

Sweep Generator Alignment

Test Equipment Required

- 1. Sweep generator, 455 kHz
- 2. Oscilloscope
- 3. Alignment tools

Procedure

- 1. Connect the sweep generator's output directly to the a-m antenna terminal.
- Connect the input cable of the oscilloscope to R321 (see Fig. 3-10) and ground on the a-m cp i-f board with alligator clips as shown in Fig. 3-10.
- 4. With the equipment connected as shown in Fig. 3-12, adjust the oscilloscope controls and generator output to provide a visible indication.

5. Turn the top core of IFT301 (see Fig. 3-10) to obtain a maximum and symmetrical response as shown in Fig. 3-11.

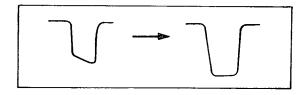

Fig. 3-11. A-m i-f strip alignment by sweep generator

Rf Signal Generator Alignment

Test Equipment Required

- 1. Signal generator, 455 kHz, a-m modulation
- 2. Oscilloscope or VTVM
- 3. Alignment tools

Procedure

- 2. Connect the rf signal-generator's output to a-m antenna terminal.
- 3. With the equipment connected as shown in Fig. 3-13, turn the top core of IFT301 (see Fig. 3-10) to obtain maximum output.

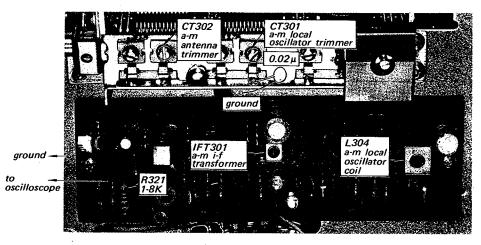

Fig. 3-10. Disabling the a-m local oscillator, a-m detector output connection and parts location

3-7. A-M FREQUENCY COVERAGE AND TRACKING ADJUSTMENT

Preparation

Remove the top cover as described in Procedure

Then, set the FUNCTION switch to AM.

Signal Generator Method

Test Equipment Required

- Standard a-m signal generator
- Loop antenna
- Ac VTVM or oscilloscope

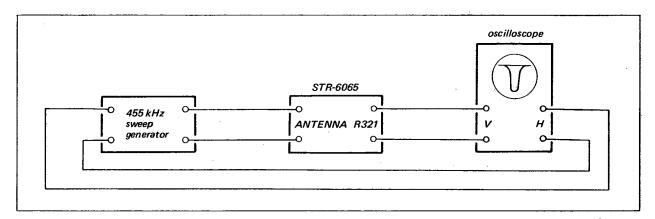

Fig. 3-12. A-m i-f strip alignment by sweep generator

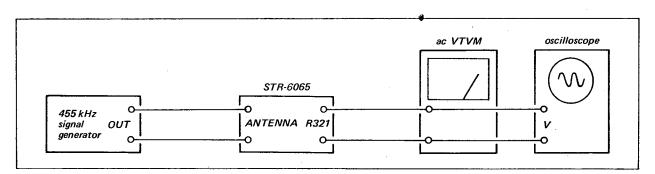

Fig. 3-13. A-m i-f strip alignment by rf generator

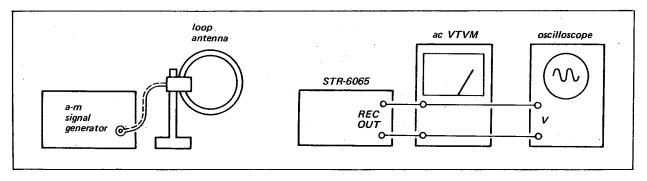

Fig. 3-14. A-m frequency coverage and tracking alignment test setup

Procedure

With the equipment connected as shown in Fig. 3-14, follow the procedures given in Tables 3-4 and 3-5 when performing this alignment with an a-m signal generator.

Off-the-Air Signal Method

Accurate dial calibration, and a frequency-coverage and tracking test can also be performed by utilizing off-the-air local a-m signals. However, before performing the following procedure, be sure that the dial pointer is correctly positioned, as in the Procedure 2-6.

Frequency Coverage Adjustment

Procedure

 Tune the receiver to the lowest-frequency station in your locality.
 Check the dial scale for a calibration accuracy of ±20 kHz from the carrier frequency. If the

- dial calibration error exceeds this limit, turn the local oscillator-coil L304 (see Fig. 3-10) slightly until optimum dial calibration is obtained.
- Tune the receiver to the highest-frequency station in your locality. If the dial calibration error exceeds ±30 kHz from the carrier frequency, adjust local-oscillator trimmer-capacitor CT301 (see Fig. 3-10) to obtain maximum calibration accuracy. Repeat the above steps two or three times.

Tracking Adjustment

- Tune the set to the station whose carrier frequency is closest to 620 kHz and adjust the position of antenna core L904 as shown in Fig. 3-15 to obtain maximum output.
- Tune the set to the station whose carrier frequency is closest to 1,400 kHz and adjust antenna trimmer CT302 to obtain maximum output. See Fig. 3-10.
- 3. Repeat the above steps two or three times.

TABLE 3-4. A-M FREQUENCY COVERAGE ALIGNMENT

SSG Coupling	SSG Frequency . and Output Level	Tuner Dial Indication	Scope Connection	Adjust	Indication
Loop antenna	530 kHz 400 Hz 30% Mod. 3,000 µV (70 dB)	530 kHz	REC OUT (J105)	OSC coil L304 See Fig. 3-10	Maximum VTVM reading
Loop antenna	1,600 kHz Same as above	1,600 kHz	Same as above	OSC trimmer CT301 See Fig. 3-10	Same as above

TABLE 3-5. A-M TRACKING ALIGNMENT

SSG Coupling	SSG Frequency and Output Level	Tuner Dial Indication	Scope Connection	Adjust	Indication
Loop antenna	620 kHz 400 Hz 30% Mod. Output level as low as possible	620 kHz	REC OUT (J105)	Position of antenna core L904 See Fig. 3-15	Maximum VTVM reading
Loop antenna	1,400 kHz Same as above	1,400 kHz	Same as above	Antenna trimmer CT302 See Fig. 3-10	Same as above

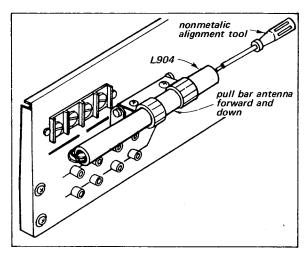

Fig. 3-15. A-m bar antenna core adjustment

3-8. POWER-AMPLIFIER ADJUSTMENT

Note: There are two adjustment items in the power amplifier. One is de-bias adjustment and the other is de-balance adjustment. These adjustments should be repeated alternately two or three times after replacing any of the power transistors until the best operation is obtained.

Dc-Bias Adjustment

Serious deficiencies in performance, such as

thermal runaway of power transistors, will result if this adjustment is improperly set.

CAUTION

To avoid accidental power transistor damage, increase the ac line voltage gradually, using a variable transformer, while measuring the voltage across emitter resistor R738 or R788 as shown in Fig. 3-16.

Check to see that the reading does not exceed 25 mV. If it does, turn off the power as soon as possible, then check and repair the trouble in the power-amplifier board.

Test Equipment Required

- 1. Dc millivoltmeter
- Variable transformer
- 3. Screwdriver with 3 mm (1/8") blade

Preparation

- Remove the top cover as described in Procedure 2-3.
- 2. Connect the dc millivoltmeter across emitter resistor R738 or R788 as shown in Fig. 3-16.

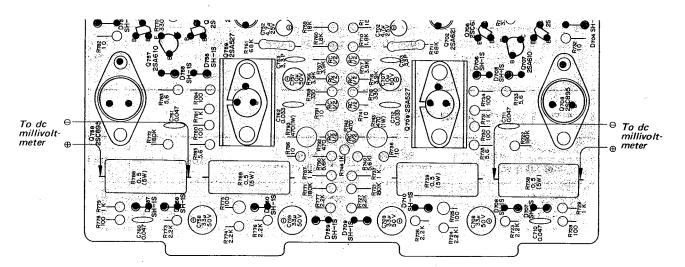

Fig. 3-16. Dc millivoltmeter connection

Procedure

1. Set the semifixed resistors (Fig. 3-17) on the power-amplifier board as follows:

RV702	
(L-CH, dc bias)	fully
	counterclockwis
RV752	
(R-CH, dc bias)	fully clockwise
RV701, RV751	
(dc balance)	mid-position

- 2. Set the SPEAKER switch to MAIN.
- 3. Set the variable transformer for minimum output.
- 4. Turn the POWER switch ON, and then increase the line voltage up to the rated value.
- Apply a drop of cement solvent to the RV701, RV702, RV751 and RV752 then wait a few seconds for the cement to dissolve.
- 6. Adjust RV702 and RV752 to obtain a 25 mV reading on the meter, and then perform the dc-balance adjustment.

Dc-Balance Adjustment

Excessive harmonic distortion at high levels will result if this adjustment is improperly set.

Test Equipment Required

- 1. Dc null meter or dc millivoltmeter
- 2. Screwdriver with 3 mm (1/8") blade

Preparation

- 1. Set the SPEAKER switch to MAIN.
- 2. Connect the dc null meter or dc millivoltmeter to the MAIN speaker output terminal.

Procedure

- 1. Turn the POWER switch ON, and then adjust RV701 (RV751) to obtain a 0V reading on the meter.
- After 10 minutes warm-up, alternately repeat this and the dc bias adjustment two or three times.
- After completing the adjustment, apply a drop of lock paint to RV701 and RV702 (RV751 and RV752).

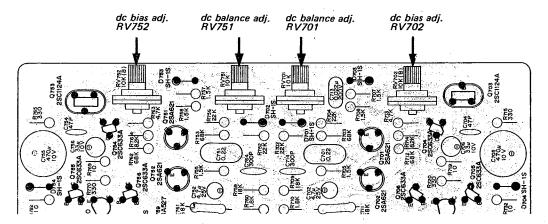

Fig. 3-17. Parts location

SECTION 4 REPACKING

The STR-6065's original shipping carton and packing material are the ideal container for shipping the unit. However to secure the maximum pro-

tection, the STR-6065 must be repacked in these materials precisely as before. The proper repacking procedures are shown in Fig. 4-1.

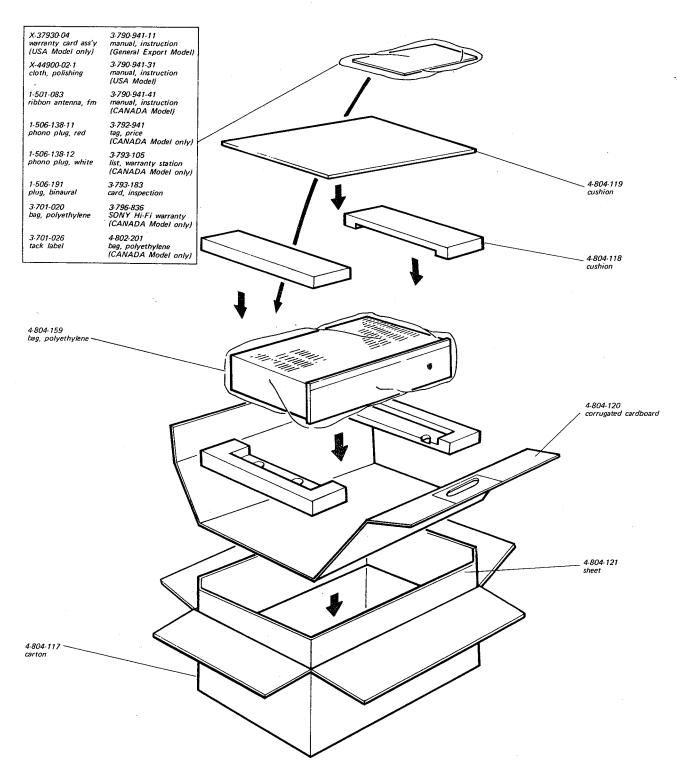

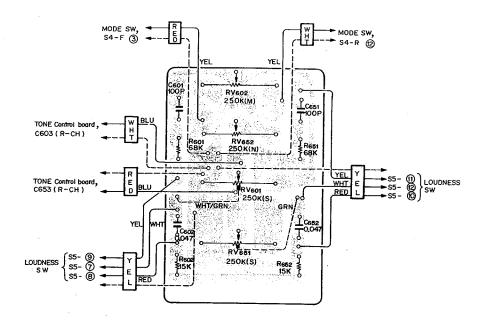

Fig. 4-1. Repacking

Description
MUTING SW
DE-EMPHASIS SW

Position ON 75 µsec

2SC710

2SK23

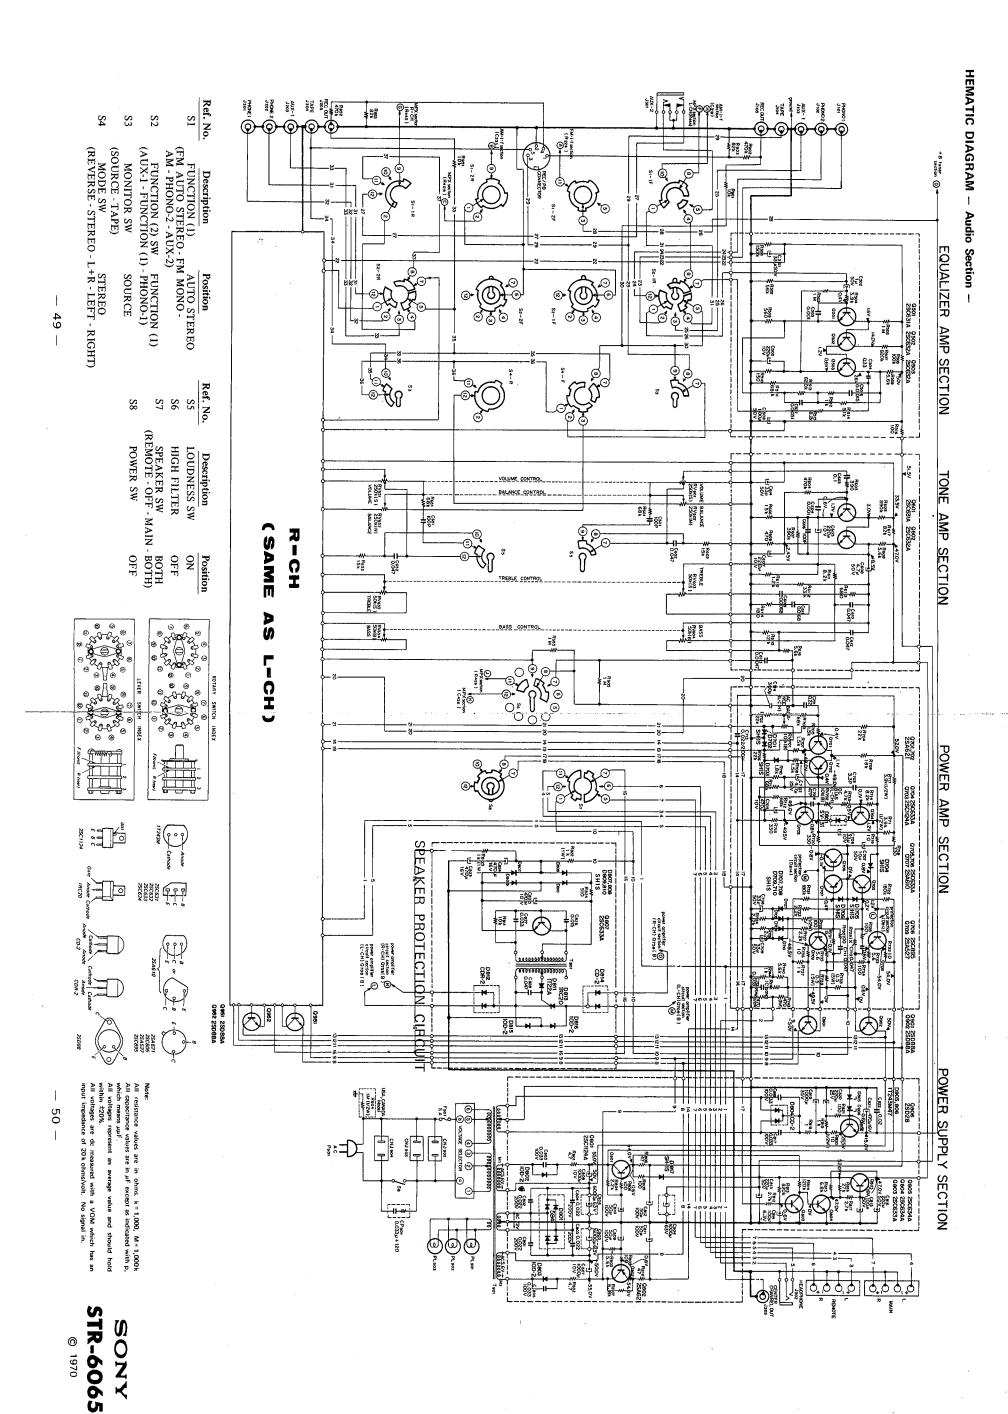

2SC403 2SC631 2SC633 2SC634

Note: All resistance values are in ohms. $k=1,000,\ M=1,000k$ All capacitance values are in μF except as indicated with p, which means $\mu \mu F$. All voltages represent an average value and should hold within $\pm 20\%$.

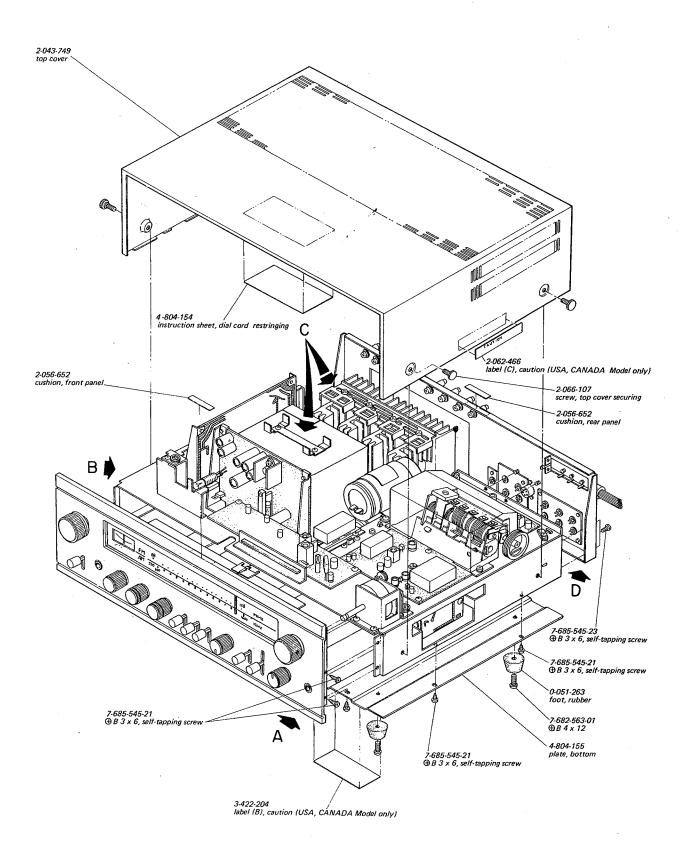

All voltages are dc measured with a VOM which has an input impedance of 20k ohms/volt. No signal in.
